Staurosporine reduced epidermal growth factor–induced PGE_2 synthesis at concentrations as low as 5 nmol/L. However, complete inhibition of the epidermal growth factor response was not achieved even at 100 nmol/L staurosporine. This result suggests the possibility that protein kinase C activation is not an absolute requirement for epidermal growth factor–induced PGE_2 production in amnion cells, but plays a more modulatory role. In an attempt to confirm the role of protein kinase C in epidermal growth factor–induced PGE_2 synthesis, we performed protein kinase C down-regulation experiments. WISH cells were exposed chronically to a high concentration of phorbol 12,13-dibutyrate. The more hydrophilic phorbol 12,13-dibutyrate was chosen for preexposure because preliminary studies had established that it was more easily washed from the cells than was phorbol 12-myristate, 13-acetate (data not shown). Phorbol 12-myristate, 13-acetate, which is more lipophilic, appears to be more tightly sequestered within the cell membrane, thus making washout more difficult. After 48 hours, by use of radioligand-binding techniques, we demonstrated an 85% reduction in tritiated phorbol 12,13-dibutyrate binding sites, suggesting a net loss of protein kinase C molecules (i.e., protein kinase C–deficient cells).[20, 25] As expected, when the cells were subsequently challenged with phorbol 12-myristate, 13-acetate, they were unable to produce PGE_2. In contrast, epidermal growth factor stimulated PGE_2 production in downregulated cells at levels comparable with cells treated with vehicle alone. In fact, there was actually a slight augmentation of the

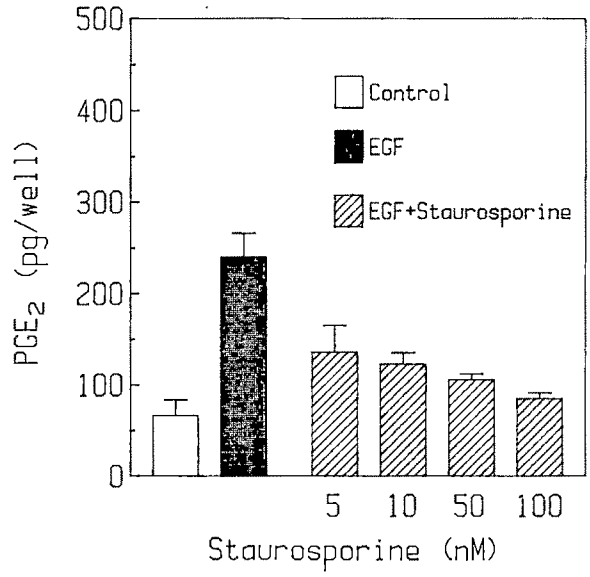

Fig. 4. Staurosporine inhibits EGF–induced PGE_2 synthesis. WISH cells were seeded into 24-well plates at 2×10^5 cells/well in F12/Dulbecco's modified Eagle's medium + 10% newborn calf serum and grown for 2 days. The cells were then fed with fresh medium containing 5 to 100 nmol/L staurosporine. Control cultures received 0.01% dimethyl sulfoxide. After a 30-minute preincubation with staurosporine the cells were treated with epidermal growth factor (10 ng/ml) for 4 hours. Media were collected and analyzed for the presence of PGE_2 by radioimmunoassay. The data represent mean ± SEM of six replicates per condition and are representative of three similar experiments.

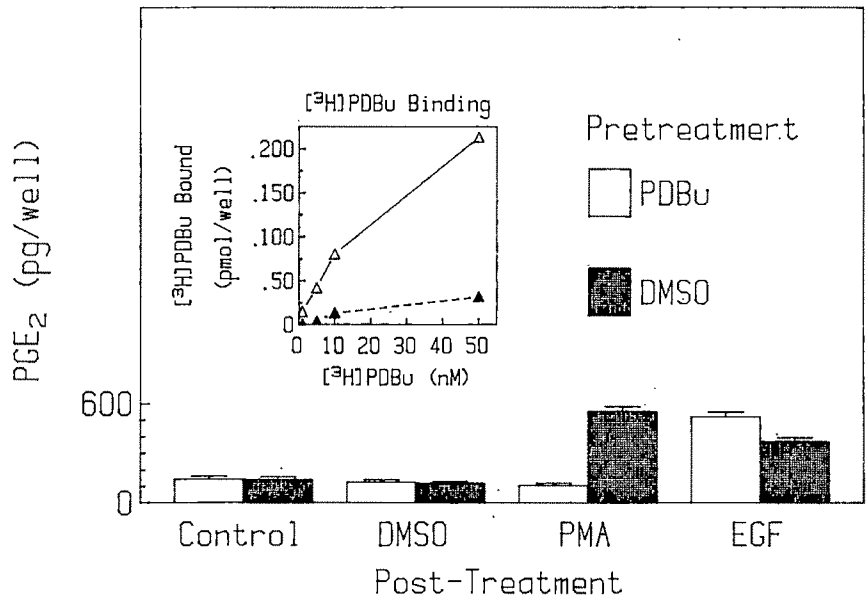

Fig. 5. Phorbol ester–induced protein kinase C down-regulation. WISH cells were seeded into 24-well plates at 2×10^5 cells/well in F12/Dulbecco's modified Eagle's medium + 10% newborn calf serum and grown for 1 day. The cells were then exposed to phorbol 12,13-dibutyrate (1 μmol/L) or dimethyl sulfoxide (0.01%). After 48 hours the cells were rinsed thoroughly with serum-free F12/Dulbecco's modified Eagle's medium and then fed fresh F12/Dulbecco's modified Eagle's medium + 10% newborn calf serum. The cells were exposed to epidermal growth factor (10 ng/ml), phorbol 12-myristate, 13-acetate (0.1 μmol/L), or dimethyl sulfoxide (0.01%). After a 4-hour stimulation period the media were collected and analyzed for the presence of PGE_2 by radioimmunoassay. The data represent mean ± SEM of six replicates per condition and are representative of two similar experiments. *Inset,* Tritiated phorbol 12,13-dibutyrate binding in protein kinase C downregulated cells. WISH cells were seeded into 12-well plates at 2.5×10^5 per well in F12/Dulbecco's modified Eagle's medium + 10% newborn calf serum and grown for 1 day. The cells were then exposed to phorbol 12,13-dibutyrate (1 μmol/L) or dimethyl sulfoxide (0.01%). After 48 hours of phorbol exposure, the cells were then rinsed with F10 + 15 mmol/L HEPES (pH 7.2) and 1 mg/ml bovine serum albumin. Tritiated phorbol 12,13-dibutyrate binding was conducted with 1 to 50 nmol/L radioligand for 1 hour at 37° C as described in Material and methods. The data represent picomoles per well of specifically bound tritiated phorbol 12,13-dibutyrate (triplicates determinations per condition) and are representative of two similar experiments. (*Solid symbols,* phorbol 12,13-dibutyrate-treated; *open symbols,* dimethyl sulfoxide-treated).

epidermal growth factor response. These results argue strongly that protein kinase C activation is not an absolute requisite for the epidermal growth factor response in amnion cells.

Margolis et al.[24] concluded, on the basis of protein kinase C down-regulation experiments, that protein kinase C did not mediate the effects of epidermal growth factor in rat kidney cells. They reported that long-term phorbol treatment failed to abolish epidermal growth factor–induced PGE_2 synthesis in the cells. However, they did find a decrease, albeit incomplete, in the epidermal growth factor/phorbol 12-myristate, 13-acetate synergism in the absence of phorbol 12-myristate, 13-acetate pretreatment (see Fig. 5 and reference 24). Although the down-regulation experiments are instructive, it must be stressed that the failure to abolish the epidermal growth factor response in protein kinase C–deficient cells is not de facto evidence for the lack of a role for protein kinase C in the epidermal growth factor transduction pathway.

Our studies showing that phorbol 12-myristate, 13-acetate markedly potentiated the epidermal growth factor response and staurosporine inhibited it provide compelling evidence that protein kinase C plays a significant modulatory role in epidermal growth factor–induced PGE_2 synthesis. Modulation of the epidermal growth factor transduction pathway by protein kinase C could occur at one of several sites. First, it is possible that phorbol-induced modulation of the epidermal growth factor receptor supersensitizes the amnion cells to epidermal growth factor. Such modulation of the epidermal growth factor receptor in WISH cells has been reported by Karasaki et al.[26] Another putative target for protein kinase C modulation of the epidermal growth factor transduction mechanism is at the level of a guanine nucleotide–binding regulatory protein (G

protein), which is thought to be interposed between the epidermal growth factor receptor and the effector system(s) with which it interacts.[27, 28] Protein kinase C–mediated G protein phosphorylation has indeed been demonstrated in other systems.[29, 30] A third possible protein kinase C target is phospholipase A_2, cyclooxygenase, or both. Experiments are currently in progress in our laboratory to define the role of protein kinase C in the liberation of arachidonic acid by phospholipase A_2 in amnion cells. Furthermore, it is possible that protein kinase C augments the induction of prostaglandin H_2 synthase by epidermal growth factor.[22]

In light of our potentiation and inhibitor studies, it is premature to discount a modulatory role for protein kinase C in epidermal growth factor–induced PGE_2 production solely on the basis of the failure of protein kinase C down-regulation to abrogate the epidermal growth factor response. It is more likely that a complex modulatory event(s) exists at one or more of the sites described to augment the epidermal growth factor response. We propose a bifurcating mechanism in which epidermal growth factor, under conditions of protein kinase C inactivation, is capable of inducing PGE_2 production alone. Under the influence of an as yet unknown endogenous activator of protein kinase C, however, the sensitivity of the amnion cells to epidermal growth factor is greatly augmented, thus leading to a markedly enhanced response.

We thank Dr. Chad Friedman for his constructive comments regarding the manuscript.

Lymphokine production during term human pregnancy: Differences between peripheral leukocytes and decidual cells

Donald J. Dudley, MD, Murray D. Mitchell, DPhil, Kathryn Creighton, BS, and D. Ware Branch, MD

Salt Lake City, Utah

Although the fetus is considered to be an "allograft," there is little information concerning the role of lymphokines in human pregnancy. Lymphokines are polypeptides secreted by stimulated lymphocytes that direct the immune response by enabling immune effector cells to communicate with each other. To characterize lymphokine production during normal human pregnancy, we isolated peripheral leukocytes and decidual lymphocyte-like cells from women undergoing repeat cesarean section at term. After stimulation with mitogen and paternal antigen for 24 hours, culture supernatants were assayed for granulocyte-macrophage colony-stimulating factor and interleukin-2 by enzyme-linked immunosorbent assay. There was no difference in the amount of interleukin-2 produced by stimulated peripheral and decidual cells. However, granulocyte-macrophage colony-stimulating factor production by stimulated decidual lymphocyte-like cells was significantly greater than granulocyte-macrophage colony-stimulating factor produced by peripheral lymphocytes. Decidual lymphocyte-like cells produced granulocyte-macrophage colony-stimulating factor both spontaneously and after stimulation with mitogen or paternal antigen, whereas peripheral leukocytes did not. This suggests that the decidua constitutes a distinct immunologic microenvironment. (Am J Obstet Gynecol 1990;163:1890-3.)

Key words: Pregnancy, lymphokines, granulocyte-macrophage colony-stimulating factor, interleukin-2

Our knowledge of the immunologic relationship between the mother and conceptus is incomplete. The conceptus appears to elicit a specific maternal immune response consisting of antibody production[1] and changes in maternal cellular immunity. This is detected as diminished proliferation of maternal peripheral blood leukocytes to irradiated paternal peripheral blood leukocytes in a mixed leukocyte culture.[2] However, some investigators believe that the important cellular immune responses to fetopaternal antigens occur in the decidua at the maternal-fetal interface.[3] It is currently thought that these decidual immune responses are beneficial to the survival of the conceptus.[4]

Cellular immune responses are characterized by the production of a variety of polypeptides known as lymphokines. Little information concerning the role of lymphokines in protecting the fetal allograft is available. Moreover, few studies have addressed the function of lymphoid cells in the human decidua. The purpose of our study was to characterize lymphokine production during normal human pregnancy, comparing the production of granulocyte-macrophage colony-stimulating factor and interleukine-2 by peripheral leukocytes with that of decidual lymphocyte-like cells. We hypothesized that the decidua constitutes a distinct immunologic environment that supports immune effector cells that produce lymphokines different from those produced by peripheral leukocytes.

Material and methods

Placentas were obtained aseptically from normal human pregnancies at term repeat cesarean section. The

membranes were isolated and rinsed in Dulbecco's modified Eagle's medium. A modification of the method described by Delvin et al.[5] was used to isolate decidual lymphocyte-like cells. The decidua adherent to the maternal side of the chorion laevae was removed by sharp dissection to yield a cell homogenate. To disperse the cells, the homogenate was mixed with 63 units of collagenase per milliliter of Dulbecco's modified Eagle's medium (100 ml total volume) at 37° C for 60 to 120 minutes. The cell homogenate was filtered through a gauze mesh to remove large debris. The cells then were centrifuged over Histopaque 1077 (Sigma, St. Louis) at 1000 *g* for 30 minutes to isolate the lymphocyte-like cell fraction. This fraction was aspirated and rinsed. The culture medium used throughout these experiments was RPMI with 1% Nutridoma-HU (Boehringer-Mannheim, Indianapolis) and antibiotics (100 U/ml penicillin G sodium, 100 U/ml streptomycin sulfate, and 0.25 μg/ml amphotericin B, Gibco Laboratories, Grand Island, N.Y.).

Heparinized peripheral blood was collected from the prospective mother and father just before the cesarean section. Peripheral blood leukocytes were isolated by standard techniques (Sigma Diagnostics, procedure 1077). The blood was diluted 1 : 1 with culture medium and then centrifuged over Histopaque 1077 at 1000 *g* for 30 minutes. The buffy coat was aspirated and rinsed.

Separate cell suspensions of maternal peripheral blood leukocytes and decidual cells were adjusted to 10^6 cells/ml and duplicate 1 ml suspensions of each were placed in 24-well tissue culture plates. The cells were stimulated with 10 μg/ml of concanavalin A and incubated for 24 hours at 37° C. Supernatants were collected and stored at −20° C until assayed.

To evaluate the maternal peripheral lymphocyte and the decidual lymphocyte-like cell response to paternal antigen, 5×10^5 maternal peripheral blood leukocytes or decidual cells were coincubated with a similar number of irradiated (2000 rads) paternal cells for 24 hours. Unstimulated control cultures were established for both cell populations in all experiments. Culture supernatants were collected and stored at −20° C until assayed.

Supernatants were assayed for granulocyte-macrophage colony-stimulating factor and interleukin-2 with commercially available enzyme-linked immunosorbent assay kits (Genzyme, Boston). The limits of sensitivity for the interleukin-2 enzyme-linked immunosorbent assay range from 0.3 ng/ml to 20.8 ng/ml. The intraassay coefficient of variation ranges from 2% to 6% and the interassay coefficient of variation is approximately 4%. For the granulocyte-macrophage colony-stimulating factor enzyme-linked immunosorbent assay, the limits of sensitivity range from 0.008 ng/ml to 1.0 ng/ml. The intraassay coefficient of variation ranges from 2% to 8%, whereas the interassay coefficient of variation ranges from 5% to 10%.

The data were evaluated statistically with the Mann-Whitney U test.

Results

Eight term pregnancies were evaluated. Granulocyte-macrophage colony-stimulating factor production by maternal peripheral blood leukocytes and decidual lymphocyte-like cells is depicted in Fig. 1. Concanavalin A–stimulated maternal peripheral blood leukocytes produced low levels of granulocyte-macrophage colony-stimulating factor (0.018 ± 0.005 ng/ml, mean ± SEM). However, decidual lymphocyte-like cells produced much greater amounts of granulocyte-macrophage colony-stimulating factor after stimulation with concanavalin A (0.2 ± 0.059 ng/ml, $p = 0.006$). Stimulation with paternal peripheral blood leukocytes also resulted in greater production of granulocyte-macrophage colony-stimulating factor by decidual cells (0.441 ± 0.262 ng/ml, $p = 0.055$ when compared with peripheral cells stimulated with paternal peripheral blood leukocytes).

Fig. 1 also suggests that the decidual cells produce granulocyte-macrophage colony-stimulating factor constitutively at low, but significant, levels (0.073 ± 0.038 ng/ml, $p = 0.01$ when compared with unstimulated maternal peripheral cells). To evaluate whether this might reflect nonspecific stimulation caused by cell processing or culture, we performed a time course experiment with concanavalin A–stimulated and unsti-

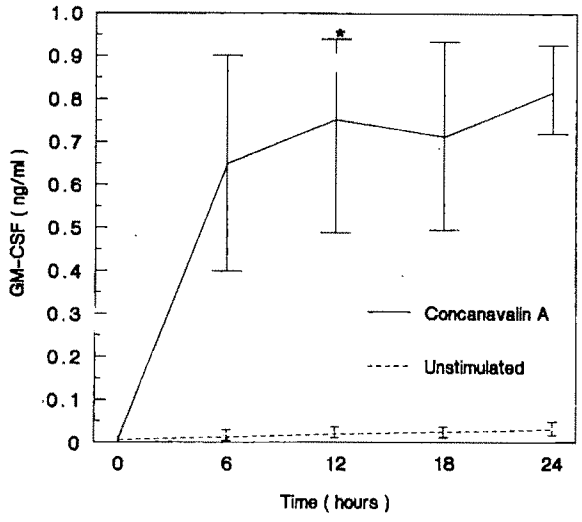

Fig. 2. Granulocyte-macrophage colony-stimulating factor production by unstimulated and concanavalin A–stimulated decidual lymphocyte-like cells over a 24-hour time period (n = 3, mean ± SE). (The standard error at the *asterisk* is 0.283.)

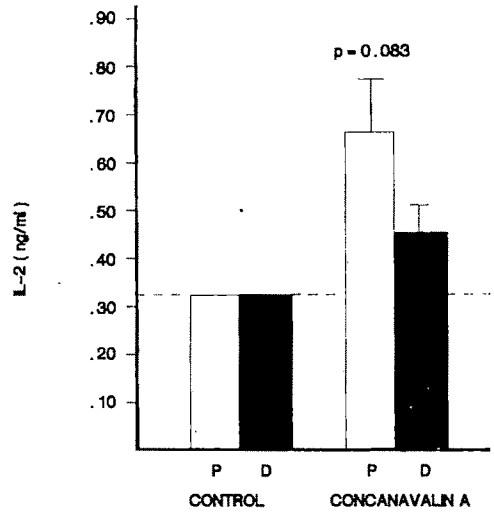

Fig. 3. Interleukin-2 production by unstimulated and concanavalin A–stimulated maternal peripheral leukocytes *(P)* and decidual lymphocyte-like cells *(D)* (n = 8). The *hatched line* delineates the lower limit of sensitivity of the assay. All values are mean ± SEM.

mulated decidual cells from three different placentas. Culture supernatants were obtained at the start of the experiment and then every 6 hours for 24 hours. The results are shown in Fig. 2. Granulocyte-macrophage colony-stimulating factor was undetectable in the cell suspensions before stimulation (time 0). However, low levels of granulocyte-macrophage colony-stimulating factor were produced by unstimulated decidual cells over 24 hours. This may represent nonspecific activation of the cells. Stimulation with concanavalin A resulted in significant production of granulocyte-macrophage colony-stimulating factor after 6 hours of incubation, indicating that the apparent nonspecific activation contributes minimally to mitogen-induced granulocyte-macrophage colony-stimulating factor production.

There was no significant difference in interleukin-2 production by maternal peripheral leukocytes and maternal decidual cells after stimulation with concanavalin A (Fig. 3). However, the P value approaches significance (p = 0.083). This lack of significance may be a result of the small sample size of the study. No interleukin-2 was detected after maternal cells were stimulated with irradiated paternal leukocytes. Irradiated paternal cells did not produce detectable amounts of interleukin-2 or granulocyte-macrophage colony-stimulating factor.

Comment

Recent observations suggest that lymphokines are important mediators of immune effector cells. Lymphokines are polypeptides secreted by activated lymphocytes with autocrine and paracrine functions to direct the immune response. They signal lymphocytes to proliferate,[6] develop cytotoxicity,[7] and produce antibody.[8] To date, more than 10 lymphokines have been described. The nature of the immune response may be dictated by the predominant lymphokine produced by stimulated lymphocytes in response to specific antigen.[9] Lymphokines also may function in a "trophic" role in certain nonlymphoid tissues.[4]

Our data indicate that immune effector cells from maternal peripheral blood and decidua differ markedly in their capacity to produce the lymphokine granulocyte-macrophage colony-stimulating factor after stimulation. Our findings also imply that assays of maternal peripheral immune cells are not reflective of the immunologic relationship between the mother and fetus. This is the first study to show that human term decidual cells produce large amounts of granulocyte-macrophage colony-stimulating factor after stimulation. Granulocyte-macrophage colony-stimulating factor is generally thought to be primarily a hematopoietic cytokine, inducing bone marrow stem cells to proliferate and differentiate.[10] However, Athanassakis et al.[11] have found that granulocyte-macrophage colony-stimulating factor produced by murine decidual cells induces proliferation of murine trophoblast.[11] This finding forms the basis of Wegmann's "immunotrophism" hypothesis.[4] According to this hypothesis, the maternal immune response to fetopaternal antigens is characterized by the secretion of granulocyte-macrophage colony-stimulating factor and other trophic cytokines. These cytokines stimulate trophoblast growth and thus maintain the fetal allograft.

Our finding that granulocyte-macrophage colony-stimulating factor is produced in large amounts by human decidual cells in response to paternal antigen supports this hypothesis. Although it is possible that the granulocyte-macrophage colony-stimulating factor produced after stimulation with paternal peripheral blood leukocytes may reflect nonspecific antigenic stimulation, we believe that this is unlikely given the large quantities produced. Whether granulocyte-macrophage colony-stimulating factor is essential to human pregnancy is unknown, but it is interesting that the heterogenous collection of decidual cells we tested maintained the capacity to produce large amounts of this lymphokine after stimulation. It seems likely that decidual granulocyte-macrophage colony-stimulating factor is of teleologic significance and it will be of scientific and academic interest to dissect the cell populations and determine the source of the granulocyte-macrophage colony-stimulating factor.

The marked differences in granulocyte-macrophage colony-stimulating factor production response between cells from the peripheral blood and the decidua suggest that the immune cells in these environments are under different regulatory control. This is consistent with our hypothesis that the maternal decidua constitutes a distinct immunologic microenvironment. In the murine immune system, cells from different lymphoid tissues produce different lymphokines.[12] An important regulatory factor is the steroid hormonal milieu found in each lymphoid tissue.[12, 13] We have recently shown that corticosteroids, dehyroepiandrosterone, and 1,25-dihydroxyvitamin D_3 at physiologic concentrations can dramatically alter lymphokine production by stimulated lymphocytes.[12, 13] Therefore markedly different lymphokine production from immune effector cells isolated from the decidua, where the cells would be influenced by the dramatic changes in the decidual steroid hormone environment, would be anticipated.

In conclusion, our data show that decidual lymphocyte-like cells differ from maternal peripheral blood leukocytes in their capacity to produce large amounts of granulocyte-macrophage colony-stimulating factor. Furthermore, we have shown a similar response to paternal antigen and this may reflect an immunotrophic maternal response to pregnancy. Further characterization of the normal lymphokine response by decidual immune effector cells and the local immunoregulatory factors that control lymphokine production will provide new insights into the normal and abnormal maternal immune responses evoked by the fetal allograft.

The effect of maternal hyperoxia on behavioral activity in growth-retarded human fetuses

Robert Gagnon, MD, Cora Hunse, RN, and Shubnum Vijan, BSc
London, Ontario, Canada

Thirteen pregnant women who subsequently were delivered of infants with birth weights less than the 3rd percentile were studied for examination of fetal heart rate and fetal activity patterns during maternal administration of oxygen at a concentration of 50% or room air for 2 hours. None of the fetuses was acidotic at birth. Maternal transcutaneous P_{O_2} levels increased from 79 ± 3 mm Hg to 158 ± 10 mm Hg for the 2 hours of observation. The results indicated that maternal hyperoxia produced sustained fetal breathing activity that was almost 100% higher than that in room air (analysis of variance, $p = 0.024$). Gross fetal body movements, fetal heart rate accelerations, and fetal heart rate variability increased significantly with increasing observation time (analysis of variance, $p < 0.01$), but were not significantly altered by maternal hyperoxia or room air. We conclude that despite significant change in fetal breathing activity, ultrasonographic observation of fetal behavioral activity during maternal hyperoxia could not be used to differentiate severely growth-retarded from normally grown human fetuses. We speculate that altered fetal heart rate and fetal body movement patterns usually associated with intrauterine growth retardation might be related to altered development of the fetal central nervous system and are not reversible during prolonged maternal administration of oxygen. (Am J Obstet Gynecol 1990;163:1894-9.)

Key words: Fetal behavior, intrauterine growth retardation, maternal hyperoxia

In pregnancies complicated with severe intrauterine growth retardation (IUGR) [small-for-gestational-age (SGA) fetuses] fetal heart rate (FHR) variability, the number of FHR accelerations, fetal breathing, and gross fetal body movements are often reduced.[1,2] It is usually believed that changes in behavioral activity in SGA fetuses are a result of chronic hypoxemia subsequent to placental insufficiency.[3] Maternal administration of oxygen has been suggested as a therapeutic approach to hypoxic fetuses,[4] and as a diagnostic test to discriminate the growth-retarded (SGA) from the normally grown [appropriate-for-gestational-age (AGA)] fetuses.[5]

The aims of this study were to determine the effects of prolonged maternal hyperoxia on FHR, FHR variability, and movement patterns in a group of SGA fetuses from 30 weeks' gestation to term.

Patients and methods

Patients. Informed consent was obtained from 21 pregnant women (investigation protocol approved by the Ethics Review Board for Research Involving Human Subjects) with singleton pregnancies between 30 and 40 weeks' gestation with clinical or ultrasonographic findings suspicious for IUGR (SGA fetus). All patients either had reliable menstrual dates or underwent ultrasonographic examination during the second trimester. Usher and McLean[6] charts were used to classify the birth weights at sea level of the fetuses studied. Growth retardation was diagnosed when birth weight was less than the 3rd percentile for gestational age. The 3rd percentile at sea level is similar to the 10th percentile for birth weights of the Denver standards[7] and is used as a cutoff point to diagnose IUGR in our center. A total of seven (33%) of the 21 participants with fetuses thought to be SGA had normal term deliveries with normal birth weights and were analyzed separately from SGA fetuses. All other participants were delivered of infants with a birth weight less than the 3rd percentile. There was no congenital anomaly or neonatal death. Umbilical cord arterial and venous blood gas values were obtained in all fetuses. Table I illustrates the characteristics and umbilical cord gas values of the SGA fetuses studied and Table II shows the primary maternal risk factors associated with IUGR. Three (75%) of four symmetrical IUGR fetuses were clinically detected before 33 weeks' gestation (early onset) and eight (88.9%) of nine asymmetrical IUGR fetuses were clinically detected at ≥33 weeks' gestation (late onset). Five (38.5%) women were delivered of infants by cesarean section and eight (61.5%) had vaginal delivery.

Experimental design. The women received a stan-

dardized 800 kcal breakfast at 8 AM or lunch at noon on two consecutive half days. All studies began 30 minutes later and were conducted in a quiet room with patients either sitting upright in bed or resting in a lateral recumbent position. The women were asked not to smoke for at least 4 hours before the studies were conducted.

Women were studied continuously for 3 1/2 hours on each of 2 half days. During the first episode of low FHR variability (mean minute range of <32 msec for >5 minutes duration) of each consecutive half day, oxygen was administered for 2 hours through a ventimask with either a 50% oxygen or 21% room air concentration of inspired oxygen. This technique allowed us to synchronize all fetuses in a state of quietness for the same length of observation (10 minutes) just before both oxygen and room air were administered. The choice of whether to administer oxygen or room air the first or second half day was made from random number tables. Maternal Po_2 was continuously measured with a transcutaneous oxygen monitor (Oxymonitor, Litton Medical Electronics, Boston, Mass.). All women were then observed for 2 hours during the time oxygen and room air were administered.

FHR and fetal activity measurements. FHR was recorded with an external monitor with a compact transducer (model 8040A, Hewlett-Packard GMBH, Boeblinger, Federal Republic of Germany) and analyzed on-line by a Sage II microprocessor (Sage Technology, Reno, Nev.) as previously described.[2] During analysis, a baseline was fitted to the heart rate record and accelerations of ≥10 beats/min for ≥15 seconds above the baseline were recognized automatically.

For each 10-minute interval, the basal FHR (in beats per minute), the mean minute range (computer-derived index of FHR variability in milliseconds), and the total gained beats (integrated area of FHR accelerations) were calculated.

Fetal breathing movements and gross fetal body movements were measured with a real-time ultrasonographic scanner (model 2130, Advanced Diagnostic Research Corp., Tempe, Ariz.) and analyzed on-line as previously described.[8] The 3.5 MHz transducer was positioned over the maternal abdomen to permit continuous observation of a longitudinal cross section of fetal chest and abdominal wall echoes.[8]

Data analysis. The basal FHR, the number of FHR accelerations of ≥10 beats/min for ≥15 seconds above the baseline, the mean minute range, and the total gained beats were determined for successive 10-minute intervals during the 68 hours of total FHR recordings. All results are presented as means ± SEMs for successive 10-minute intervals before and during administration of oxygen or room air. Portions of records that could not be analyzed because of FHR signal loss of >30% or patient interruption were not included. These portions made up 6.8% of the total study time. One woman was delivered of an infant before the second half day of the study and was excluded for the purpose of analysis.

Measurements of the percentage of time spent making gross fetal body movements and the percentage of time spent making breathing movements were calculated for each 10-minute interval. Portions of movement records that could not be analyzed because of technical problems or patient interruption made up 6.0% of the total time involved.

Statistical significance between groups after administration of oxygen or room air was determined by a two-factor analysis of variance with repeated measures, comparing overall means and each of the 10-minute intervals with biomedical data processing 5V statistical software.[9]

Fetal breathing and gross fetal body movements. The mean time from the onset of the study until an

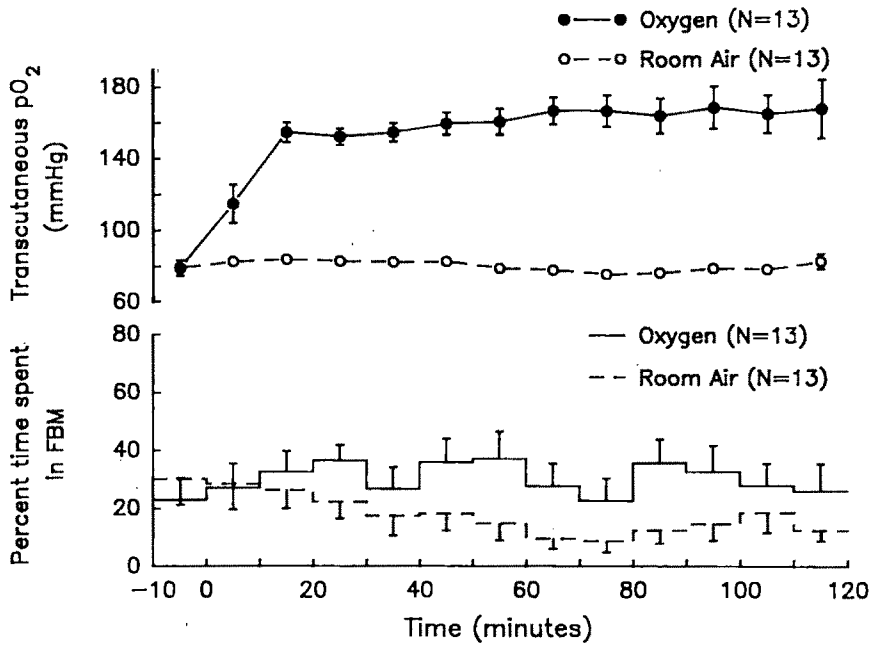

Fig. 1. Mean maternal transcutaneous Po_2 (mm Hg) ± SEM was plotted in 10-minute intervals before and after maternal administration of oxygen *(solid lines)* or room air *(dashed lines)* **(top).** Mean incidence of fetal breathing movements *(bottom)* was also plotted on same time scale. *Horizontal bar* indicates time during which oxygen or room air was administered.

episode of low FHR variability occurred was 21 ± 4 minutes before administration of oxygen compared with 25 ± 3 minutes before room air. During maternal hyperoxia the mean transcutaneous oxygen increased from 79 ± 3 mm Hg to a maximum of 158 ± 10 mm Hg at time 0 plus 15 minutes and remained above that of room air during the 2 hours of observation (analysis of variance, $p < 0.001$, Fig. 1, top).

Mean fetal breathing incidence was similar during the 10 minutes before administration of oxygen (23.0% ± 6.7%) or room air (30.1% ± 9.1%). During the 2 hours oxygen was administered, the mean incidence of fetal breathing movements was 33.5% ± 4.5%, which was significantly higher than that of 18.4% ± 3.3% during room air (analysis of variance, $p = 0.024$). However, there was no significant effect of time on the incidence of fetal breathing movements during maternal hyperoxia, suggesting that fetal breathing movements were sustained during hyperoxia but not markedly increased above preoxygen levels (Fig. 1, bottom). In contrast, fetal breathing movements decreased progressively to 12.3% ± 5.5% between 110 and 120 minutes after administration of room air was started (Fig. 1, bottom).

The mean incidence of gross fetal body movements per 10 minutes increased significantly from 3.9% ± 1.3% before administration of oxygen to a maximum of 11.6% ± 2.5% 40 minutes after the onset of maternal administration of oxygen (analysis of variance, $p = 0.002$; Fig. 2, top). A similar increase in the mean incidence of gross fetal body movements was found during administration of room air and there was no significant difference between the two groups (oxygen and room air, respectively, Fig. 2, top).

FHR accelerations, FHR variability, and basal FHR. The mean total gained beats per 10 minutes, which was 4.2 ± 2.1 before oxygen was administered, increased to a maximum of 21.5 ± 6.1 between 30 and 40 minutes after the onset of maternal hyperoxia (analysis of variance, $p = 0.01$; Fig. 2, bottom). Similarly, the mean number of FHR accelerations per 10 minutes increased from 0.7 ± 0.2 before administration of oxygen to a maximum of 2.4 ± 0.6 accelerations between 30 and 40 minutes of maternal hyperoxia (analysis of variance, $p = 0.004$). The mean 10-minute mean minute range, which was 29.1 ± 2.6 msec before administration of oxygen, increased progressively to 46.9 ± 6.2 msec at 40 minutes of maternal hyperoxia (analysis of variance, $p < 0.001$). No significant difference was found between room air and oxygen in FHR variability and FHR accelerations. The mean basal FHR was 136 ± 3 beats/min before oxygen and did not change during the 2 hours of maternal administration of oxygen or room air.

Relationship between fetal behavioral activity and FHR patterns. Fig. 3 summarizes characteristics of FHR and fetal activity patterns during the 2 hours in which SGA fetuses received oxygen or room air. During

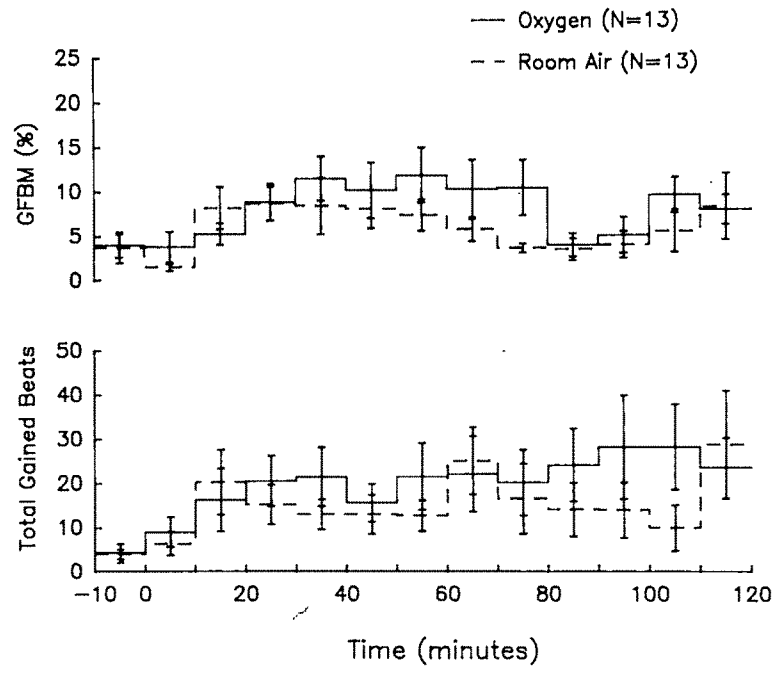

Fig. 2. Mean incidence of gross fetal body movements *(GFBM)* was plotted in 10-minute intervals before and after maternal administration of oxygen *(solid lines)* or room air *(dashed lines)* (top). Mean total gained beats (bottom) was also plotted on same time scale. *Horizontal bar* indicates time during which oxygen or room air was administered.

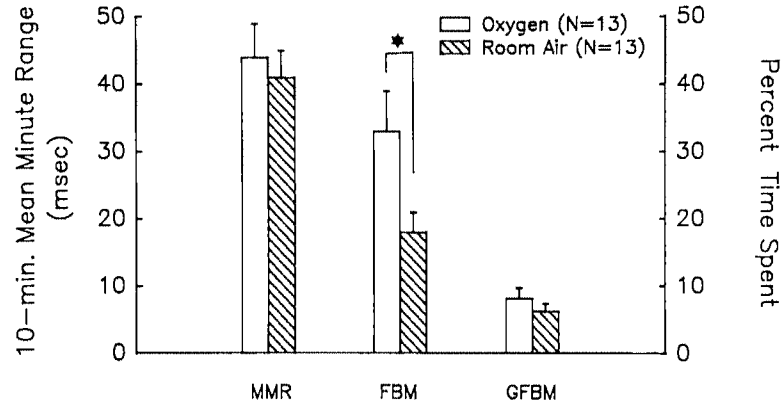

Fig. 3. Mean incidence of fetal breathing movements *(FBM)*, mean incidence of gross fetal body movements *(GFBM)*, and mean 10-minute mean minute range *(MMR)* were plotted during 2 hours of maternal administration of oxygen or room air ($*p < 0.05$).

the 2 hours of maternal hyperoxia, the fetuses made breathing movements 33.5% ± 4.5%, which was significantly higher than during the time room air was administered (18.4% ± 3.3%) (analysis of variance, $p = 0.024$). However, it was important that the incidence of gross fetal body movements and the 10-minute mean minute range were not significantly different between oxygen and room air (room air values: 6.2% ± 1.2% for gross fetal body movements and 41.5 ± 4.1 msec for 10-minute mean minute range value, respectively, Fig. 3).

In the seven fetuses who were subsequently born as AGA infants, the mean fetal breathing movements incidence was 36.4% ± 5.4% during the 2 hours room air was administered, which was not significantly different from the 38.3% ± 4.5% during maternal hyperoxia. Similarly, the mean incidence of gross fetal body movements, the mean 10-minute range, and the mean total gained beats were not significantly altered during maternal administration of oxygen (9.1% ± 1.5% for gross fetal body movements, 50.5 ± 2.3 msec for 10-minute mean minute range value, and 21.0 ±

2.3 for total gained beats) compared with room air (10.1% ± 1.7%, 54.5 ± 2.9 msec, and 22.4 ± 3.1, respectively).

Comment

The data show that in a group of severely growth-retarded fetuses, maternal administration of oxygen (inspired oxygen 50%) was associated with sustained fetal breathing movements compared with room air. In contrast, fetal body movements and computer-based indexes of FHR accelerations and FHR variability were not significantly altered under similar experimental conditions. In fetuses that were subsequently delivered as AGA infants, the incidence of fetal breathing movements, the incidence of gross fetal body movements, and FHR variability did not change significantly during maternal hyperoxia.

The periodicity in rest-activity cycles of the human fetus is well accepted and has provided the physiologic basis for fetal assessment.[10] Our data and others[1, 2] indicated that such cycles are present in SGA fetuses between 30 and 40 weeks' gestation. When observations of fetal activity were started during a period of rest, with increasing observation time, SGA fetuses became more active, experienced more FHR accelerations with increased FHR variability reaching a peak between 30 and 40 minutes (Fig. 2). We recently described the same patterns of behavioral activity with the use of similar experimental design in a group of healthy term AGA fetuses.[11] However, maternal hyperoxia sufficient to double maternal transcutaneous P_{O_2} did not alter fetal rest-activity cycles in growth-retarded fetuses.

Ruedrich et al.[12] recently reported an increase in fetal body movements in IUGR fetuses during maternal hyperoxia reaching a peak 30 minutes after oxygen was discontinued. Because there was no control group without oxygen in the experiment, it is possible that the increase in fetal body movements described in the study was a result of the normal periodicity of rest-activity cycles rather than oxygen alone.

A significant portion (50%) of the SGA fetuses being tested and delivered during the present study were premature (<37 completed weeks' gestation), as expected with severe IUGR. The organization of biophysical activities into clearly differentiated behavioral states as defined by Nijhuis et al.[13] usually occurs after 36 weeks' gestation in AGA fetuses. In contrast, the same group of investigators reported the absence of states differentiation in up to 80% of SGA fetuses at 40 weeks' gestation.[14] Although prematurity at the time of the studies may account for the differences between our observations and others,[12] it is very unlikely that the establishment of behavioral states would have occurred in SGA fetuses even in term and that results would have been different at later gestational age. Moreover, incidence of fetal breathing movement is not used as a state variable[13] because in contrast to the fetal lamb, it is present in both quiet and active sleep states in the human fetus.[13]

Although fetal body movements and FHR accelerations usually occur together, there is some evidence that the control of fetal breathing movements could be dissociated from other biophysical variables used to assess fetal health and behavioral activity. In the fetal lamb, prolonged hypoxemia suppresses fetal breathing activity without significant change in electrocortical activity.[15] Fetal breathing activity is suppressed by maternal administration of ethanol[16] and stimulated by infusion of glucose[17] in the healthy term human fetus. In both experimental conditions, fetal body movement and FHR patterns are not altered.[16-17] In this study, as in others,[18] the incidence of fetal breathing movements in SGA fetuses was significantly higher during maternal hyperoxia than that in room air. It is not clear by which mechanisms maternal administration of oxygen can produce sustained breathing activity. It has been reported in work by Boddy et al.[19] in the fetal lamb, that during maternal hyperoxia there is an increase in fetal P_{CO_2} without change in maternal P_{CO_2} only if the fetus was previously hypoxemic. Hypercapnia is known to be a potent stimulus of fetal breathing activity and could be responsible for the sustained breathing activity. However, this mechanism is speculative and remains to be confirmed.

It has been shown that fetuses with severe IUGR have a reduction in long-term FHR variability, FHR accelerations, and fetal movements.[1-3] Maternal hyperoxia did not have any significant effect on these biophysical variables in the present study. This suggested that altered behavioral activity associated with IUGR might be related to an abnormal development of the fetal central nervous system and is not reversible during prolonged maternal administration of oxygen.

Our observation that maternal hyperoxia is associated with sustained fetal breathing incidence but without change in body movements and FHR accelerations in SGA fetuses during the third trimester, does not support the concept that ultrasonographic observation of fetal behavioral activity during maternal hyperoxia could be used to differentiate SGA from AGA fetuses as recently suggested.[12] Moreover, it is possible to speculate that chronic maternal administration of oxygen used as fetal therapy for SGA fetuses[4] may not improve fetal outcome at a time IUGR is clinically or ultrasonographically diagnosed. These important questions remain to be answered with appropriate clinical trials before suggesting the use of maternal hyperoxia for intrauterine evaluation or treatment.

We thank Mrs. Maria De Sousa for her excellent technical assistance.

Bound volumes available to subscribers

Bound volumes of the AMERICAN JOURNAL OF OBSTETRICS AND GYNECOLOGY are available to subscribers (only) for the 1990 issues from the Publisher, at a cost of $56.00 ($79.00 international) for Vol. 162 (January-June) and Vol. 163 (July-December). Shipping charges are included. Each bound volume contains a subject and author index and all advertising is removed. Copies are shipped within 60 days after publication of the last issue in the volume. The binding is durable buckram with the JOURNAL name, volume number, and year stamped in gold on the spine. *Payment must accompany all orders.* Contact Mosby–Year Book, Inc., Circulation Department, 11830 Westline Industrial Drive, St. Louis, Missouri 63146-3318, USA; phone (800) 325-4177, ext. 7351.

Subscriptions must be in force to qualify. Bound volumes are not available in place of a regular JOURNAL subscription.

Observations on the cause of oligohydramnios in prolonged pregnancy

Kenneth J. Trimmer, MD, Kenneth J. Leveno, MD, Mark T. Peters, MD, and Mary Anne Kelly, RN

Dallas, Texas

There is increasing evidence that implicates reduced amnionic fluid volume as a major determinant of fetal risk in prolonged pregnancy. We sought to determine whether reduced fetal urine production might be associated with oligohydramnios in pregnancies that reach 42 weeks or more. Ultrasonographic measurements of the fetal bladder were obtained every 2 to 5 minutes for 1 hour in 38 gestations verified to be at least 42 weeks. Oligohydramnios was present in eight of the prolonged pregnancies. Similar measurements were performed in 15 normal pregnancies delivered by elective repeat cesarean section between 38 and 40 weeks' gestation. Hourly fetal urine production rates were calculated with sequential bladder volume measurements. The result of this investigation suggest that diminished fetal urine production is associated with oligohydramnios in prolonged pregnancy. The mechanism by which fetal urine production is reduced in prolonged pregnancy remains unknown. A likely possibility is reduced fetal swallowing because of already diminished amnionic fluid volume, the latter a result of placental senescence. (Am J Obstet Gynecol 1990;163:1900-3.)

Key words: Postterm pregnancy, fetal urine production, oligohydramnios, ultrasonography

Perinatal morbidity is significantly increased in postterm pregnancies and oligohydramnios appears to be an important factor.[1] The inability to accurately measure diminished amnionic fluid volume has led to the adoption of ultrasonographic semiquantitative estimations of volume such as the four-quadrant method[2] or the measurement of the deepest vertical pocket.[3] Because fetal urine is a major source of amnionic fluid, measurement of hourly fetal urine production rates may provide information on amnionic fluid dynamics in prolonged pregnancies. Indeed, realtime ultrasonography has been used to quantitate hourly fetal urine production rates in normal term pregnancies[4] and in pregnancies complicated by intrauterine growth retardation.[5] The purpose of this investigation was to measure and compare fetal urine production rates in normal term pregnancies, postterm pregnancies with normal amnionic fluid volume, and those with oligohydramnios.

Material and methods

Women with singleton pregnancies verified to be 42 to 43 weeks were recruited from the Obstetrical Complications Clinics at Parkland Memorial Hospital. Labor was induced the next morning. Gestational ages were calculated from a calendar of recorded last menses and two or more of the following: (1) first trimester examination, (2) fundal height measurements between 20 and 30 weeks' gestation, (3) DeLee-Hillis fetoscopic fetal heart tones detected between 18 and 20 weeks' gestation, and (4) ultrasonography performed before 24 weeks' gestation. In addition, normal singleton pregnancies at 38 to 40 weeks' gestation scheduled the next morning for repeat cesarean section were selected to serve as controls.

All pregnancies received ultrasonographic examination with a 3.5 MHz linear transducer (Ultramark 4, Advanced Technology Laboratories, Bothell, Wash.). Biparietal diameters, femur lengths, and abdominal perimeters were obtained in each pregnancy. Oligohydramnios was diagnosed when the maximum vertical dimension of the largest amnionic fluid pocket measured $\leq$ 1 cm.[3]

Hourly fetal urine production rates were calculated once in each pregnancy and within 24 hours of delivery or labor induction. The method used was identical to that previously described by Rabinowitz, Peters, Vyas, et al.[4] Briefly, Rabinowitz and colleagues used real-time ultrasonography to obtain measurements of the fetal bladder every 2 to 5 minutes for 1 hour. The greatest longitudinal bladder dimension (sector a) was measured as shown in Fig. 1. The transducer was then rotated 90° and the bladder scanned cephalad and caudad as shown in Fig. 2. The greatest trans-

6/6/24745

verse distance (sector b) and anterior-posterior dimension (sector c) of the fetal bladder were then measured. Bladder volumes were calculated from these three sector measurements with the formula for an ovoid sphere: $4/3\ \pi \times a/2 \times b/2 \times c/2$, where a = longitudinal bladder, b = greatest transverse bladder distance, and c = anterior-posterior dimension of the fetal bladder. These bladder volumes were plotted versus time and then simple linear regression analysis was used to compute hourly fetal urine production rates on the basis of the filling phase of the first micturition cycle.

Obstetric and neonatal outcomes were obtained from the hospital records. In addition, neonatal examinations were performed by the author (K. J. T.) to specifically note physical signs of postmaturity. The infant was classified as postmature if it fulfilled all criteria of any stage of Clifford's descriptions for postmaturity.[6]

Statistical analysis was performed on a VAX 8800 computer with an interactive statistical package (UTSTAT), University of Texas Southwestern Medical Center at Dallas) with the use of Newman-Keuls multiple comparison analysis, the Student t test, and χ^2 where appropriate. Significance was considered when probabilities were < 0.05.

Results

A total of 38 pregnancies diagnosed to be 42 weeks in duration were studied. Oligohydramnios was diagnosed in eight of these pregnancies. Another 15 pregnancies delivered by elective cesarean section made up the control group. Maternal characteristics that included age, parity, and race did not differ significantly among the pregnancies. Approximately 80% of the women were Hispanic or African-American. All infants were live born and there were no neonatal deaths. One infant of a 42-week pregnancy without oligohydramnios was diagnosed to have Hirschprung's disease. Transient tachypnea of the newborn developed in another infant of a 42-week pregnancy with normal amnionic fluid volume.

Shown in Table I are selected pregnancy outcomes in postterm pregnancies with and without oligohydramnios compared with normal term gestations delivered by repeat cesarean section. Mean birth weights, although greater in those pregnancies that reached 42 weeks, were not significantly different between the study groups. Newborn condition as reflected by umbilical artery blood pH results are also shown in Table I and did not differ significantly among the study groups. Approximately 25% of the postterm pregnancies with or without oligohydramnios were delivered by cesarean section for either dystocia or fetal distress in labor. Meconium was found in the amnionic fluid of 13% ($n = 2$) of pregnancies delivered by elective

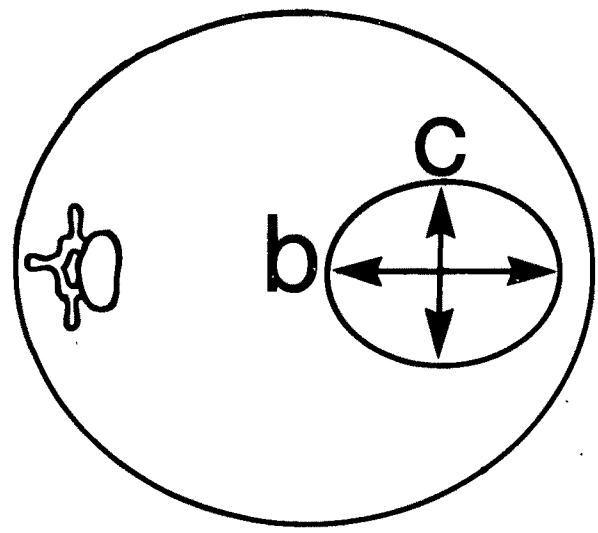

Fig. 2. Transducer is rotated 90° to measure greatest transverse and anterior-posterior bladder dimensions, *sectors b and c,* respectively.

cesarean section and in 13% ($n = 4$) of the postterm pregnancies with normal amnionic fluid volume. In contrast, meconium-stained amnionic fluid was present in 38% ($n = 3$) of the postterm pregnancies with oligohydramnios. This difference was significant ($p < 0.001$). Similarly, infants with features of the postmaturity syndrome were more common in 42-week pregnancies with oligohydramnios. Specifically, 88% ($n = 7$) of these latter pregnancies resulted in postmature infants compared with 37% ($n = 12$) when normal amnionic fluid volumes were present ($p < 0.001$).

The hourly fetal urine production rates, mean maximum bladder volumes (maximum fetal bladder vol-

Mean (SD) bladder filling time (minutes)	25 (8)	49 (10)	23 (5)	<0.001

ume immediately before micturition), and mean cycle lengths (time for empty fetal bladder to fill and empty) for the 53 pregnancies in this study are shown in Table II. The mean maximum bladder volume was 36 ml and did not vary significantly among the study groups. Fetal micturition, observed on 93 occasions, was generally completed in <30 seconds. Postmicturition bladder volumes <25% of the maximum bladder volume were considered complete emptying and occurred in 87% of the fetuses. The mean hourly fetal urine production rates observed in the postterm pregnancies with normal amnionic fluid volumes was identical to those measured in normal term gestations. However, a precipitous reduction (50%) in fetal urine production was observed in those postterm pregnancies complicated by oligohydramnios. Specifically, hourly fetal urine production rates decreased from 56 ml/hour to 24 ml/hour ($p < 0.001$) when oligohydramnios was present. This diminished fetal urine production rate correlated directly with a prolonged fetal bladder filling cycle (the time to fill and empty the fetal bladder). The mean duration of the 46 cycles observed in the term and postterm pregnancies with normal amnionic fluid was 24 minutes compared with 49 minutes observed in six cycles in the postterm pregnancies with oligohydramnios ($p < 0.001$).

Comment

Oligohydramnios is increasingly emphasized as a hallmark of perinatal pathology in a large number of pregnancy complications,[7-9] and is particularly relevant in prolonged pregnancy because the volume of amnionic fluid diminishes as gestation reaches term and beyond. In this study, the hourly fetal urine production rate was significantly less in the postterm pregnancy complicated by oligohydramnios, whereas fetal urine production in the postterm pregnancy with normal amnionic fluid was no different than that in normal pregnancy at term.

Although amnionic fluid dynamics are not completely understood in human beings, it is known that fetal urination and swallowing play prominent roles in

the regulation of fluid volume. However, other regulatory factors are also considered important in the maintenance of amnionic fluid volume. For example, Gilbert and Brace[10] proposed an *intramembranous pathway* in which amnionic fluid is absorbed by the fetal blood perfusing the membranes and surface of the placenta. This was hypothesized to explain their findings that infusion of warmed distilled water into the amnionic fluid of ewes resulted in a decrease in fetal serum osmolality. In a more recent report, Brace studied ovine fetal blood volume, urine production, swallowing, and amnionic fluid volume in response to fetal intravascular infusion of isotonic saline solution.[11] He observed a large increase in fetal urine production concomitant with doubling of fetal swallowing. Very little of the intravenously administered saline solution remained in the fetus (1% to 2%), approximately 30% remained in the amnionic fluid, and the bulk of the infused saline solution presumably was transferred into the mother. Because fetal-maternal osmolalities did not change, Brace postulated that shifts of fetal fluids were governed by unknown placental mechanism(s) more complex than simple osmotic diffusion. These findings may have significance in the interpretation of our results now reported in prolonged human pregnancy. Specifically, our finding of markedly diminished fetal urine production when oligohydramnios complicates postterm pregnancy could conceivably be a consequence of diminished swallowing because of prior reduction of amnionic fluid volume, the latter a result of the placental factors hypothesized by Brace. That is, advanced placental maturation or senescence associated with postmaturity may be the placental factor that permits loss or transfer of amnionic fluid, presumably, into the mother.

In conclusion, prolonged pregnancy complicated by oligohydramnios is associated with marked reduction in fetal urine production. We hypothesize that this decrease in fetal urine flow is a consequence, as opposed to a primary event, of already reduced amnionic fluid volume that results from placental senescence because of prolonged gestation.

A mechanism leading to reduced lung expansion and lung hypoplasia in fetal sheep during oligohydramnios

Richard Harding, PhD, Stuart B. Hooper, PhD, and Kerry A. Dickson, PhD
Melbourne, Australia

Our aim was to determine the mechanism whereby oligohydramnios causes reduced fetal lung expansion and eventual lung hypoplasia. We studied 20 fetal sheep during 2 to 9 days of oligohydramnios produced by drainage of amniotic and allantoic fluids during the last third of gestation. Oligohydramnios led to a reversible reduction in lung liquid volume of 19.5% within 48 hours. During oligohydramnios tracheal pressure, relative to amniotic pressure, rose by 1.7 mm Hg ($p < 0.001$); pressures also tended to rise in the fetal pleural space and abdomen, relative to amniotic pressure, and to fall in the amniotic sac. Pressure increments, relative to amniotic pressure, which normally occur in the fetal trachea, pleural cavity, and abdomen during nonlabor uterine contractions, were significantly increased by 1.9 to 2.5 mm Hg during oligohydramnios. Oligohydramnios increased flexion of the fetal thoracolumbar spine, quantified as a reduction in the ratio of spinal radius of curvature to spine length (0.76 in controls vs 0.40 after oligohydramnios, $p < 0.001$). In three sets of twins, only the fetus exposed to oligohydramnios was affected. A similar degree of spinal flexion imposed on normal fetal sheep cadavers increased abdominal (1.6 mm Hg), pleural (1.5 mm Hg), and tracheal (2.0 mm Hg) pressures, and caused a significant reduction in fetal lung expansion. We conclude that oligohydramnios in fetal sheep increases spinal flexion, leading to compression of abdominal contents, upward displacement of the diaphragm, and lung compression, favoring loss of fetal lung liquid. These changes, which are accentuated during nonlabor uterine contractions and are reversible, may lead to pulmonary hypoplasia if prolonged. (AM J OBSTET GYNECOL 1990;163:1904-13.)

Key words: Oligohydramnios, fetal lung hypoplasia, fetal posture, uterine contractions, lung liquid

Fetal lung hypoplasia, defined as a reduction in lung weight per unit body weight, is a common consequence of oligohydramnios. In human pregnancy, lung hypoplasia most frequently results from oligohydramnios due to premature rupture of the membranes or to urinary tract abnormalities in the fetus.[1-4] Lung hypoplasia can be produced experimentally by removal of amniotic fluid in rabbits,[5,6] guinea pigs,[8] monkeys,[9] and sheep.[10,11] Although a causal relationship between oligohydramnios and fetal lung hypoplasia has been well established, there remains some controversy as to the mechanism involved.

Fetal lung development is strongly influenced by physical factors,[12] in particular fetal breathing movements and lung expansion by liquid. An impairment of fetal breathing movements[13-15] or a diminished degree of lung expansion[16,17] both result in reduced fetal lung growth. In a recent study in sheep, we showed that prolonged oligohydramnios during the last third of gestation leads to a reduced volume of fetal lung liquid (i.e., reduced lung expansion), whereas fetal breathing movements were not impaired.[11] In an analysis of endocrine and fluid balance responses to oligohydramnios in sheep we have been unable to account for the observed reduction in fetal lung liquid volume.[18]

Although the mechanisms whereby fetal lung liquid volume is reduced during oligohydramnios are not clear, our previous studies indicate that physical factors, such as lung compression, are likely to be involved. Therefore we monitored fetal sheep in utero to determine the effects of short-term, reversible oligohydramnios on pressures that act on the fetal lungs, the volume of lung liquid, and on the flow of this liquid. Oligohydramnios was induced by drainage of amniotic and allantoic fluids, and the reversibility of the fetal effects was assessed by replacement of an appropriate volume of the drained fluids. We also quantified the effects of oligohydramnios on the posture of the fetus in utero. To determine the influence of these changes on the fetal lungs, we examined in fetal cadavers ex utero the effects of imposing changes in posture similar to those induced by oligohydramnios on pressures that act on the lungs and on lung expansion.

Material and methods

We used 31 fetal sheep from 28 ewes, the mating dates of which were known. Two types of study were performed: (1) measurement of oligohydramnios-induced changes in pressures, lung liquid production, flow and volume, and spinal flexion in chronically prepared fetuses in utero, and (2) measurements of changes in pressures and lung expansion in fetal cadavers during manipulation of fetal posture. The experimental procedures were approved by the Monash University Committee for Ethics in Animal Experimentation.

Chronic preparations. Aseptic surgery was performed with established techniques,[11, 18, 20] on 20 fetuses in 20 pregnant ewes at 101 to 115 days (mean, 107.9 ± 1.0 SEM days) after mating (term, 146 days). In each fetus we implanted ascending and descending catheters into the midcervical trachea; these were subsequently connected externally to form a tracheal "loop" that enabled the measurement of tracheal pressure with a T-connector and fluid flow with a flowmeter.[19, 20] These procedures did not interfere with the function of the fetal upper respiratory tract. Liquid-filled open-tipped or balloon-tipped catheters were implanted into the fetal intrapleural (eight fetuses) and intraperitoneal (eight fetuses) spaces for pressure recording. A catheter was attached to the skin in the midneck region of all fetuses for the measurement of amniotic sac pressure, and another catheter (open or balloon-tipped) was attached to the external surface of the uterus (eight fetuses) to measure maternal intraperitoneal pressure. This was subtracted electronically from amniotic sac pressure to record corrected amniotic sac pressure.

Fine stainless steel electrodes were sewn into the muscle of the fetal diaphragm (six fetuses) and uterus (14 fetuses) to monitor the electromyographic activity of the diaphragm as an index of fetal breathing movements[19, 20] and uterine contractions,[21] respectively. In each preparation, two large diameter silicone rubber catheters (3.2 mm inner diameter, 6.4 mm outer diameter) with protected side ports[11, 18] were attached to the fetal skin at the base of the neck and over the rump; another was implanted within the allantoic sac. These were used to drain amniotic and allantoic fluids by gravity into sterile collection bags placed level with the floor of the sheep's cage.

Study procedure. Fetal surgery was followed by a recovery period of at least 5 days during which no measurements were made. Each study consisted of a control period (1 to 2 days), a period of amniotic and allantoic fluid drainage (2 to 9 days; mean, 3.7 ± 0.3 days), starting at 108 to 138 days' gestation (120 ± 1.2), and a recovery period that followed the reintroduction of drained fluids. The volume replaced was that drained during the first 24 hours of drainage, because this approximates the volume initially contained in the sacs.[11, 18]

In eight experiments we drained fluids a second time, at least five days after restoration of normal amniotic and allantoic fluid volumes. In four of these, the second period of oligohydramnios was used to determine changes in fetal posture that resulted from oligohydramnios. Fetal blood gas values (P_{O_2}, P_{CO_2}, pH), hemoglobin content, and hematocrit were measured daily from samples of carotid arterial blood.

Measurements during in utero studies. Catheters were attached to pressure transducers (Statham P23ID) that were fixed in the same horizontal plane, level with the midpoint of the ewe when standing. Fetal pressures (tracheal, pleural, abdominal) were displayed on a polygraph after subtraction of amniotic sac pressure; 10 mm Hg produced a pen deflection of 20 mm. Amniotic sac pressure (after subtraction of maternal intraperitoneal pressure) was recorded at the same sensitivity. During periods of oligohydramnios, pressures were measured only after the drain catheters had been blocked for 2 to 4 hours, and the amniotic sac catheter flushed with 5 to 10 ml saline solution (to prevent hydrostatic effects). Immediately before each recording period and at 8- to 12-hour intervals, the pressure monitoring circuits were rebalanced and recalibrated. The drift in these circuits was <0.5 mm Hg per 24 hours.

Electromyographic electrodes were connected to differential amplifiers and filters. The fetal diaphragmatic electromyograph was displayed as an integral that reset when full-scale deflection was reached. The number of integrator resets per hour was quantified to give an index of fetal breathing movements. The uterine electromyograph was displayed on the polygraph after filtering to indicate (along with amniotic pressure) nonlabor uterine contractions.

The net efflux of tracheal fluid over 12 to 24 hours was taken as a measure of the production of fetal lung liquid.[19, 20] Because it seemed likely that the flow of lung liquid at the time of nonlabor uterine contractions may be altered by oligohydramnios we also measured net tracheal flow during at least 20 to 35 contractions over 24-hour periods. Lung liquid volume was assessed twice daily in five fetuses by draining liquid from the lower tracheal cannula into a sterile graduated container before returning it to the lungs. During oligohydramnios lung liquid volume was measured only after the amniotic and allantoic drain catheters had been blocked for 2 to 4 hours. In four fetuses, changes in lung liquid volume were measured during two periods of oligohydramnios, and during one period of amniotic and allantoic fluid replacement. In four fetuses, lung liquid volume was also measured by dye dilution[22] during the control periods.

Measurement of spinal curvature. We measured the degree of fetal spinal flexion, between the rump and

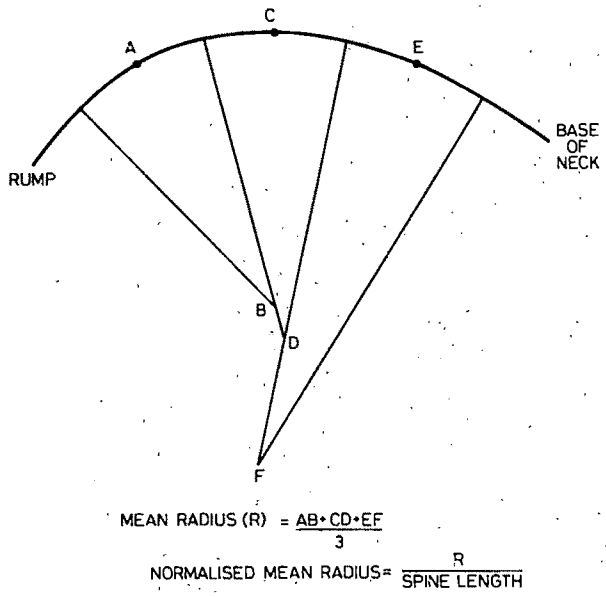

Fig. 1. Technique for quantification of spinal curvature in fetal sheep. Spinal outline between base of neck and rump was divided into four equal segments. Four right bisectors were drawn, and three radii obtained *(AB, CD, EF)*. Mean radius was normalized to permit comparisons between fetuses of different sizes by dividing mean radius by spine length.

upper thorax at postmortem examination while the fetus was in utero. The outline of the spine was traced onto paper and the mean radius of curvature computed; this was normalized by expressing it in relation to the length of the spine over which curvature was measured (Fig. 1). We confirmed the measurements from radiographs of the intact uterus that still contained the fetus after it was removed from the ewe and frozen.

Studies on fetal cadavers ex utero. Fourteen fetuses were studied ex utero <1 hour after death to assess the effects of increased spinal flexion on fetal pressures (n = 6) and lung expansion (n = 12). Six fetuses were implanted with liquid-filled balloon-tipped catheters in the pleural space and abdominal cavity. In each fetus we inserted a catheter into the lower trachea to measure tracheal pressure (n = 6) or to measure the efflux of tracheal fluid (n = 12), taking care to minimize the loss of lung liquid. The fetal upper respiratory tract was not in circuit in the studies on cadavers. However, the absence of the normal resistance presented by the upper respiratory tract[23] would be expected to alter only the time-course of changes in fetal pressures and lung liquid volume caused by spinal flexion. Pressures were recorded on a polygraph while we manipulated the fetuses into three arbitrarily chosen degrees of spinal flexion (mild, moderate, severe). The starting (resting) position was that adopted naturally by the cadaver when it was placed on its side. To measure the change in lung expansion caused by changes in fetal posture we connected the tracheal cannula to a vertical graduated tube. Fluid leaving the lungs entered the tube and its volume was determined at the three stages of spinal flexion. The spinal outline was drawn at each position and the normalized mean radius of curvature was calculated.

Data analysis. In each experiment we measured basal pressures at 5-minute intervals (n = 30 to 35) during the control, oligohydramnios, and recovery periods, excluding episodes of uterine motility. Pressure changes during uterine contractions (n = 20 to 30) were measured at the peak of each contraction. Fetal pressures were measured during apnea or during episodes of fetal breathing movements at end-expiration. Data on pressures and lung liquid production and flow were taken during the last day of the control period, the second day of the oligohydramnios period, and the first 24 hours of the recovery period, starting 6 hours after the return of fluids. We analyzed differences between data obtained during control, oligohydramnios, and recovery periods with the Student t test (paired or unpaired as appropriate) or two-way analysis of variance (ANOVA) followed by a Newman-Keuls multiple range test. Data from cadavers were analyzed with the same tests. Data are presented as mean ± SEM throughout.

Results

Volumes of fluids drained. Volumes of amniotic and allantoic fluids that drained were measured after 24 hours and 48 hours during 15 experiments in 12 sheep. During the first 24 hours of drainage 1149 ± 129 ml had drained from the sacs, of which 1028 ± 111 ml was amniotic fluid. After 48 hours the drained volume was 1634 ± 186 ml, of which 1442 ± 138 ml was amniotic fluid.

Fetal condition throughout experiments. Each fetus was considered to be in good condition throughout the in utero experiments, as indicated by blood gas values, pH, hematocrit, and hemoglobin. Values obtained during the control period (Po_2 24.8 ± 1.1 mm Hg; Pco_2 48.6 ± 2.0 mm Hg; pH 7.335 ± 0.007; Sao_2 61.3 ± 2.8; hemoglobin 9.4 ± 0.3 gm/dl; hematocrit 33.6 ± 2.1%) did not differ significantly from those obtained during the oligohydramnios or recovery periods. Fetal breathing activity was assessed in six experiments (five fetuses); the numbers of diaphragmatic electromyographic integrator resets/hour (arbitrary units) were 21.3 ± 3.0 (control), 26.0 ± 5.7 (oligohydramnios), and 20.5 ± 4.1 (recovery). Although the mean value during oligohydramnios was higher than that during the control period, it was not significantly so ($0.05 < p < 0.10$). However, there was a significant re-

duction in fetal breathing movements after fluids were replaced ($p < 0.025$).

Basal pressure measurements. Basal pressures in the amniotic sac and in the fetal trachea, pleural cavity, and abdominal cavity during the control, oligohydramnios, and recovery periods are shown in Table I. During oligohydramnios the mean amniotic sac pressure, relative to the ewe's intraperitoneal pressure, was 1.0 ± 0.6 mm Hg lower than that during the control period and 1.1 ± 0.5 mm Hg lower than that during the recovery period, but these changes were not significant ($p < 0.1$, <0.05, respectively). The fetal tracheal pressure, relative to amniotic sac pressure, was significantly elevated by 1.69 ± 0.32 mm Hg during oligohydramnios ($p < 0.001$) from a control value of 1.27 ± 0.21 mm Hg, and was significantly reduced by 1.14 ± 0.19 mm Hg after fluids were returned ($p < 0.001$). Tracheal pressures during the control and recovery periods were not significantly different. Fetal intrapleural and abdominal pressures, relative to amniotic sac pressure, increased slightly during oligohydramnios and declined after the return of fluids, but the pressure changes were not significant (Table I).

Pressures during nonlabor uterine contractions. The mean interval between the start of successive nonlabor uterine contractions increased from 35.6 ± 9.7 minutes in the control period to 46.7 ± 12.6 minutes during oligohydramnios ($p < 0.025$, nine experiments, five animals). During the recovery period the interval between contractions (41.3 ± 4.9 minutes) was not significantly different from that during the oligohydramnios or control periods. The duration of the contractions (nine experiments, six animals) increased from a mean control value of 8.0 ± 0.6 minutes to 9.0 ± 0.8 minutes during oligohydramnios ($p < 0.025$), and decreased significantly to 8.1 ± 0.8 minutes after the return of fluids ($p < 0.01$).

Pressure increments above baseline were measured in the amniotic sac and fetal compartments at the peak of nonlabor uterine contractions during the control, oligohydramnios, and recovery periods (Table I, Fig. 2). Amniotic sac pressure increased during contractions by 4.1 ± 0.5 mm Hg in the control period and was not altered significantly during the oligohydramnios or recovery periods. During uterine contractions fetal tracheal pressure, relative to amniotic sac pressure, increased by 1.7 ± 0.5 mm Hg during the control period, 4.0 ± 0.2 mm Hg during the oligohydramnios period, and 1.8 ± 0.2 mm Hg during the recovery period. That is, oligohydramnios led to an additional increase in tracheal pressure during contractions of 2.3 ± 0.4 mm Hg over the increments that occurred during the control period ($p < 0.001$). This change was reversed when drained fluids were replaced ($p < 0.001$).

The increments in intrapleural pressure, relative to amniotic pressure, during contractions were as follows: control, 1.2 ± 0.5 mm Hg; oligohydramnios, 3.6 ± 0.4 mm Hg; recovery, 1.4 ± 0.3 mm Hg. That is, the pressure increments increased significantly by 2.5 ± 0.4 mm Hg ($p < 0.001$) as a result of oligohydramnios, and decreased after drained fluids were returned ($p < 0.001$). Fetal abdominal pressure also increased above amniotic pressure levels during nonlabor uterine contractions during the control (1.2 ± 0.4 mm Hg), oligohydramnios (3.0 ± 0.7 mm Hg), and recovery (0.7 ± 0.3 mm Hg) periods. During oligohydramnios, the pressure increments increased significantly by 1.9 ± 0.5 mm Hg ($p < 0.025$); when fluids were returned the pressure increments declined significantly ($p < 0.025$) to control values.

Lung liquid production, flow, and volume. The effects of oligohydramnios on fetal lung liquid production and flow during uterine contractions are shown in Table II). Lung liquid production, measured from net tracheal fluid efflux over at least 12 hours, was not significantly altered by oligohydramnios. Tracheal fluid flow rate was measured during uterine contractions in the same experiments during the second day of fluid drainage. Oligohydramnios led to an increase in the mean rate of fluid efflux (milliliters per hour) of 6.8 ±

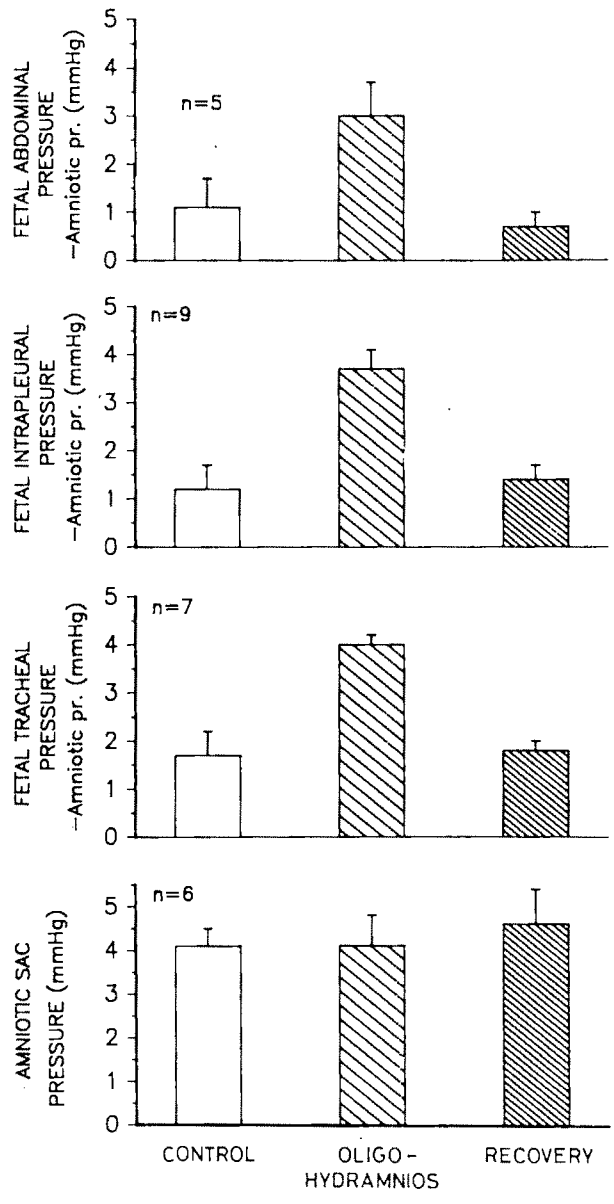

Fig. 2. Increments in fetal pressures and amniotic sac pressure during nonlabor uterine contractions in fetal sheep under control conditions, during oligohydramnios and after replacement of drained fluids (recovery). During oligohydramnios pressure increments in fetal abdomen, pleural space, and trachea rose significantly in relation to amniotic sac pressure. Increments in amniotic sac pressure during contractions did not alter as result of oligohydramnios.

3.1 ml/hour during nonlabor contractions ($p < 0.005$, paired Student t-test) compared with the control period. The rate of efflux during contractions was lower in the recovery period than during oligohydramnios, but the difference was not significant.

The volume of liquid that could be drained from the fetal lungs was measured twice daily during the control, oligohydramnios, and recovery periods (Table II, Fig. 3). Because of normal variability in lung liquid volume

Table II. The effect of oligohydramnios on lung liquid production, tracheal flow during nonlabor uterine contractions, and drained lung liquid volume

	Control	*Oligohydramnios*	*Recovery*
Production (ml/hour, $n = 6$ experiments)	2.82 ± 0.71	3.64 ± 0.58	3.44 ± 0.69
Flow during contractions (ml/hour, $n = 6$ experiments)	5.21 ± 1.03	12.02 ± 3.86	7.67 ± 0.96
Volume (ml, $n = 9$ experiments)	35.3 ± 4.2	28.4 ± 3.9	—
Volume (ml, $n = 5$ experiments)	—	31.2 ± 4.6	43.9 ± 6.9

Data on lung liquid production and flow were obtained in four fetuses; data on lung liquid volume were obtained in a separate group of five fetuses.

with time, a mean value was obtained for each fetus from the four values obtained over 2 days that preceded oligohydramnios, during the first 2 days of oligohydramnios, and during the 2 days after the replacement of fluids. During nine periods of oligohydramnios in five fetuses, starting at 112 to 128 (119 ± 2) days' gestation, there was a reduction of drained lung liquid volume from 35.3 ± 4.2 ml to 28.4 ± 3.9 ml ($p < 0.025$). Replacement of amniotic and allantoic fluids at 121 ± 3 days' gestation led to an increase in lung liquid volume from 31.2 ± 4.6 ml to 43.9 ± 6.9 ml (five experiments, five fetuses; $p < 0.001$). The volume of lung liquid drained was 84.2% ± 8.6% of the volume obtained by the dye-dilution method (nine experiments, four fetuses).

Spinal curvature in utero. Spinal curvature was measured in seven fetuses (aged 123 to 130 days) that had not been subjected to oligohydramnios, and in seven fetuses (aged 125 to 138 days) that had been subjected to 2 to 9 days of oligohydramnios (Table III, Fig. 4). When the mean radius of curvature was normalized for spine length, values obtained in fetuses killed during oligohydramnios (0.40 ± 0.02) were significantly smaller than those in control fetuses (0.76 ± 0.07, $p < 0.001$). In each of three sets of twins included in the group described above, the spinal radius was less in the fetus exposed to oligohydramnios than that in the control twin (Table III).

Studies on fetal cadavers. The aim of these studies was to measure the effects of imposed changes in spinal flexion on pressures that affect the fetal lungs and on lung expansion. In the resting position, pressures in the abdomen, pleural cavity, and trachea were equal to

atmospheric pressure. Pressure changes in six fetuses (aged 123 to 141 days) at the three stages of spinal flexion are shown in Table IV. The mean pressures in each compartment increased incrementally when the spine was increasingly flexed; however, the differences between pressures during mild and moderate degrees of flexion were not significantly different. At each level of spinal flexion, the mean pressures measured in the trachea tended to be greater than those in the other fetal compartments, although the differences were not significant.

In a separate study, changes in fetal liquid lung volume were studied in 12 fetal cadavers between 123 and 141 days' gestation (Fig. 5, Table IV). At the resting position a pressure head of 1 to 2 cm water was created in the tracheal liquid. With increasing degrees of spinal flexion (mild, moderate, severe) increasing amounts of luminal liquid left the lungs via the trachea in each fetus. With mild, moderate, and severe flexion, the volume leaving the lungs represented 5.8%, 11.0%, and 18.0%, respectively, of the initial volume of lung liquid (determined by drainage); these volumes were significantly different from each other. There was no significant effect of gestational age on the change in lung liquid volume during spinal flexion (Fig. 5).

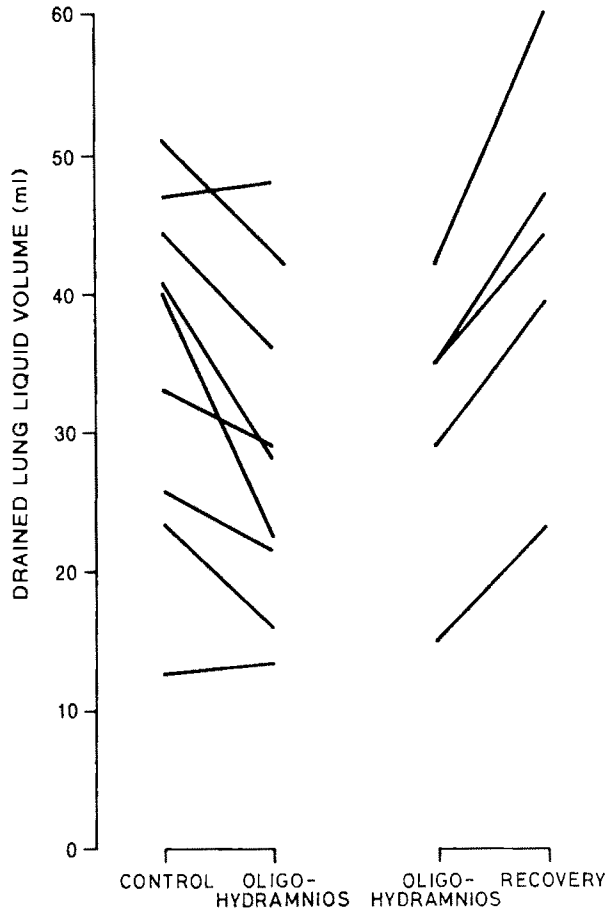

Fig. 3. Changes in drained lung liquid volume in five fetal sheep in response to oligohydramnios and to replacement of drained amniotic and allantoic fluids (i.e., recovery). In four of five fetuses there were two periods of oligohydramnios. Each data point is mean of four values obtained over 48 hours.

Comment

In our previous study[11] we showed that prolonged oligohydramnios resulted in reduced lung expansion in fetal sheep, an observation that we have now confirmed during short-term oligohydramnios. A reduction in fetal lung expansion, if prolonged, is known to result in lung hypoplasia,[16, 17] and is the most likely explanation for oligohydramnios-induced lung hypoplasia. We now present data that show a mechanism whereby oligohydramnios leads to reduced fetal lung expansion and that the effects are established quickly and can be readily reversed by replacement of fluids into the fetal sacs. Our observations indicate that oligohydramnios causes a rise in fetal pulmonary "airway" pressure, relative to amniotic sac pressure, principally as a result of an alteration in fetal posture (i.e., increased spinal flexion) imposed by a reduction in uterine volume. Our data also indicate that in twin pregnancies only the fetus without an adequate volume of surrounding fluid is affected.

The increase in tracheal fluid pressure, relative to amniotic pressure, that occurs during oligohydramnios would be expected to lead to an increased efflux of liquid from the lungs via the trachea. Such a flow of liquid would be very difficult to detect under basal conditions because of the normally large variability of tracheal flow in the fetus.[20] However, we were able to detect an increased rate of efflux of fluid during nonlabor uterine contractions when the pressure difference between the lungs and amniotic sac increases for several minutes. The measurement of an increased tracheal pressure also indicates that the fetus is able to resist, at least partially, the loss of luminal liquid from

Table IV. *Upper,* increments in fetal pressures during increasing degrees of spinal flexion in six fetal sheep cadavers ex utero (mean age, 134 ± 3.2 days); *lower,* efflux of lung liquid via the trachea with increasing degrees of spinal flexion in 12 fetal sheep cadavers (mean age, 132.2 ± 2.1 days)

Normalized spinal radius (R/L) is given for each fetal position.

its lungs. The loss of lung liquid would be opposed (but could not be prevented) by the upper airway, which normally offers a resistance to the efflux of tracheal liquid, particularly in the absence of fetal breathing movements.[23] It is possible that an increase in the resistance of the upper airway during uterine contractions may have contributed to the observed increase in tracheal pressure.

Our data on changes in fetal posture that result from oligohydramnios and from fetal cadavers subjected to similar postural changes allow us to propose an explanation for increased tracheal pressure and reduced lung liquid volume associated with oligohydramnios. In fetal cadavers with liquid-filled lungs, increased flexion of the spine between the upper thorax and the rump, caused graded increases in pressure in the abdomen, pleural cavity, and trachea. Most of this flexion occurs in the abdominal segments. We propose that as the abdominal contents become compressed the diaphragm is displaced into the thorax, thereby compressing the lungs. In cadavers we observed that this effect was increased by apposition of the upper hind limbs to the abdominal wall; this postural feature was noted in some of the fetuses post mortem after oligohydramnios.

In fetuses killed during oligohydramnios the degree of spinal flexion, quantified as the ratio of mean spinal radius to spine length, was approximately equal to moderate spinal flexion that we imposed on cadavers. This produced a rise in tracheal pressure of 2.0 mm Hg, which was slightly greater than the pressure rise measured in the fetal trachea in utero, in the absence of uterine muscle activity. The pressure increments in the abdomen and pleural space of cadavers during moderate flexion were also greater than the nonsignificant increments in these compartments in vivo during oligohydramnios. These differences between in utero and ex utero measurements are probably a result of those in cadavers being made in a closed system (i.e., lung liquid could not escape via the trachea), whereas in utero the fetal trachea can communicate with the amniotic sac. Moderate spinal flexion in cadavers caused a loss of 5 ml of luminal liquid from the lungs. This was less than we measured during 48 hours of oligohydramnios, possibly because the lungs of cadavers are less expanded, due to unavoidable escape of lung liquid after death of the fetuses. The volumes of fluid that we subsequently drained from the lungs of cadavers supports this. However, the studies on fetal cadavers clearly show that posture is an important determinant of basal lung capacity, as it is in the adult.[24] In particular, our studies show that increasing spinal flexion, similar to that induced by oligohydramnios, can lead to compression of the fetal lungs. In the absence of an upper airway it is to be expected that this would lead to reduced lung expansion, but even with an intact, functioning upper airway and continuing fetal breathing movements, a reduction in fetal lung expansion must occur, although the time course may be longer.

Our measurement of a nonsignificant reduction in amniotic sac pressure is in agreement with our earlier study.[11] In human pregnancy, a reduction in amniotic sac pressure has been reported during oligohydramnios,[25] which may be expected to accentuate the driving force favoring loss of liquid from the lungs. However, a fall in amniotic sac pressure in the absence of fetal postural changes would be expected to be accompanied by a similar reduction in fetal pressures. That fetal pressures did not fall but tended to rise indicates that some independent rise in pressures occurred within the fetus. We propose that this is a result of an imposed change in fetal posture.

We have shown that the effects of oligohydramnios on the fetal lungs are increased by nonlabor contractions of the uterus, which are a normal feature of the latter half of pregnancy in many species including human beings.[21, 26, 27] Although they are of low intensity (typically <5 mm Hg) they are known to exert effects on the fetus, including alteration of thoracic dimensions,[28] reduced fetal oxygenation,[29] and reductions in uterine blood flow.[28] Ultrasonographic observations on fetal pygmy goats showed that these contractions also cause increasing degrees of spinal flexion.[27] This accords with our observations of increased pressures in the fetal abdomen, pleural cavity, and trachea, particularly during oligohydramnios. Even when normal volumes of amniotic and allantoic fluids are present, uter-

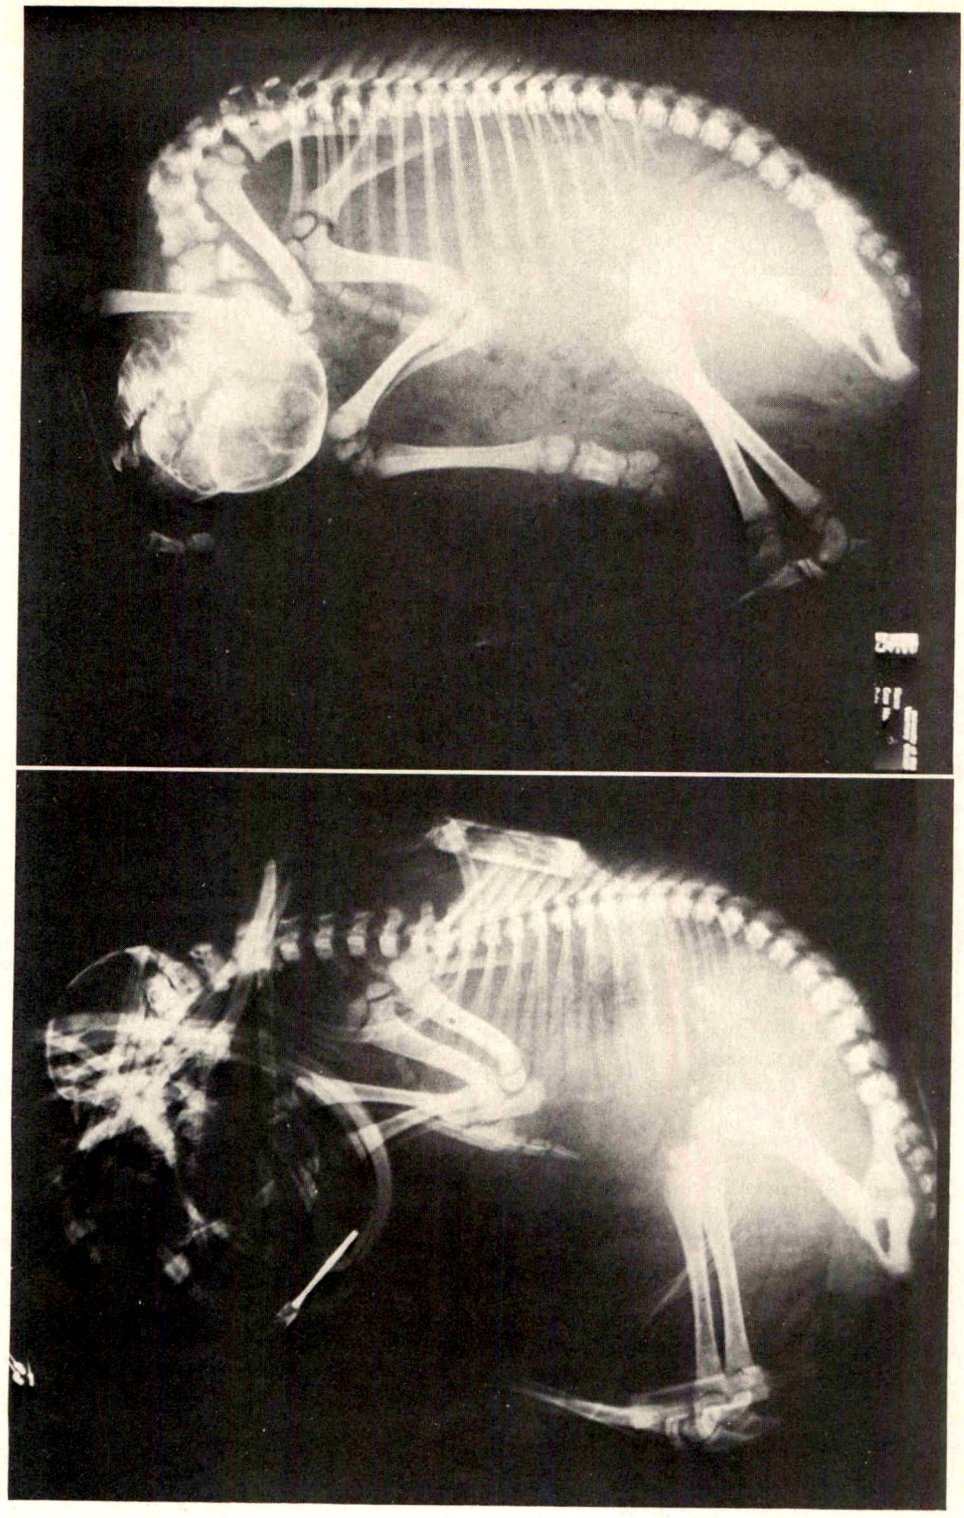

Fig. 4. Radiographs of fetal sheep in utero after removal from ewe. *Upper*, control fetus aged 135 days. *Lower*, fetus aged 129 days after 9 days of oligohydramnios. Note greater degree of spinal flexion in fetus in presence of oligohydramnios.

ine contractions are associated with increased pulmonary airway pressure and increased flow of liquid from the lungs, particularly when the contractions coincide with episodes of fetal breathing movements.[30] The efflux of lung liquid during contractions is increased during oligohydramnios presumably because of the greater pressure difference between the lungs and amniotic sac; the contractions are also slightly longer. Whether

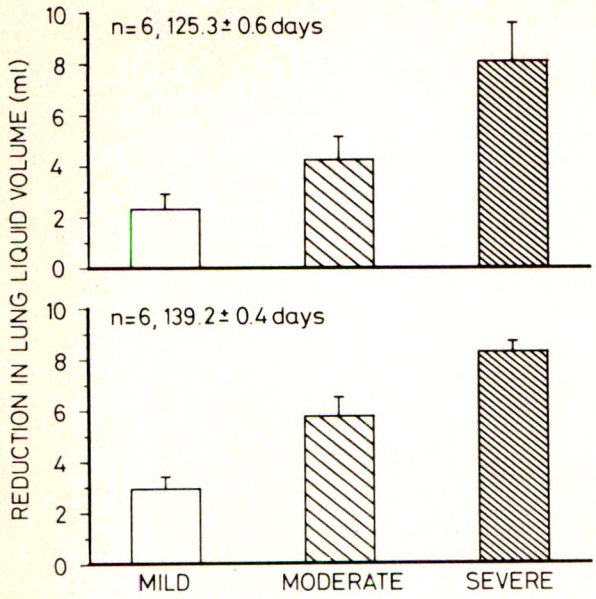

Fig. 5. Reduction in lung liquid volume in 12 fetal sheep cadavers ex utero at two age groups (*upper*, 123 to 127 days and *lower*, 136 to 141 days) in response to three stages of imposed spinal flexion (mild, moderate, severe). In both groups, increasing spinal flexion led to increased loss of liquid from lungs via trachea.

this additional loss of lung liquid contributes to the reduction in lung liquid volume during oligohydramnios cannot be determined at present. That the fetus is able to resist the compressive effects of these contractions, at least partially, is shown by the measured increases in tracheal pressure. This resistance is likely to be a result of fetal muscular activity in the upper respiratory tract, because we observed in one fetus a greatly increased efflux of lung liquid via the trachea during contractions after it was inadvertently killed in utero during oligohydramnios.

The effects of oligohydramnios on fetal pressures were evident within 12 to 24 hours of the start of drainage of amniotic and allantoic fluids, and a reduction of lung liquid volume was measured over the first 48 hours. This is to be expected if the observed effects are indeed a result of the physical consequences of reduced uterine dimensions. Similarly, it is to be expected that the fetal pressure and lung volume changes should be reversible, which we found them to be. Normal fetal pressures (basal and during uterine contractions) were recorded within 2 to 4 hours of reexpanding the fetal fluid sacs. It is of interest that an increase in the volume of amniotic fluid above normal in pregnant sheep will reduce the extent of changes in thoracic dimensions during nonlabor uterine contractions.[31]

Lung liquid production was not affected by short-term oligohydramnios during the present study and therefore cannot have contributed to the observed changes in pulmonary pressures or volume. This is in agreement with our earlier study[11] in which there was no reduction in lung liquid production until after 48 hours of oligohydramnios. It is likely that the reduced lung liquid production we previously observed during prolonged oligohydramnios was principally a result of reduced lung growth and was not a response to alterations in the endocrine or fluid-balance status of the animals.[18]

We conclude that oligohydramnios in ovine pregnancy can lead to an increased pressure gradient between the pulmonary airways of the fetus and the amniotic sac, favoring the loss of lung liquid via the trachea, and a reduction in lung expansion. These changes are probably maintained by increased spinal flexion imposed on the fetus by a reduced uterine volume, and are augmented during recurring nonlabor contractions of the uterus. The effects on the fetus are reversible and support the clinical management of the fetus exposed to oligohydramnios by intraamniotic infusion of fluids.[32]

Soluble factors produced by isolated first-trimester chorionic villi directly inhibit proliferation of T cells

Richard K. Silver, MD, Jane M. Turbov, BA, Judith A. Beaird, BS, and Joseph Golbus, MD

Evanston, Illinois

Supernatants from human trophoblast cultures have been reported to be both suppressive and stimulatory of mitogen-induced T-lymphocyte transformation. These discordant observations have been attributed to methodologic differences among laboratories, but may instead relate to inadvertant cellular contamination during long-term culture. Retrieval of chorionic villi for genetic analysis has provided an opportunity to evaluate the immunoregulatory activity of the isolated villus preparation, unencumbered by extended culture techniques. Primary cytotrophoblast cultures were established from karyotypically and clinically normal pregnancies and the supernatants were recovered. Allogenic mononuclear cells, stimulated by phytohemagglutinin, were uniformly inhibited by trophoblast supernatant (mean inhibition, 34.3%). This inhibition was verified in one-way, mixed lymphocyte cultures and suppression of T cells occurred in a dose-dependent fashion over a range of trophoblast supernatant concentrations. No evidence of suppressor T-cell induction by trophoblast supernatant was noted with the use of both phenotypic studies of lymphocytes incubated with trophoblast supernatant and a functional suppressor T-cell inducer assay. We believe that the immunoregulatory properties of trophoblast supernatants identified with the use of these methods more closely approximate the paracrine function of the in situ villus. (Am J Obstet Gynecol 1990;163:1914-9.)

Key words: Trophoblast, lymphocytes, immunosuppression

There exists considerable evidence that maternal immunologic tolerance of the fetal allograft is, in part, dependent on the intervening trophoblast barrier. The influence of this fetally derived tissue is likely diverse and includes both passive and active immunoregulation.[1-4] The presumed "nonantigenicity" of the outer syncytiotrophoblast and its ability to bind and neutralize offending antibodies are two examples of passive immunoregulation.[5,6] In contrast, synthesis and release of immunologically potent mediators may modulate both the systemic host response and the local intrauterine environment.[7,8] Contemporary investigations that have focused on mediator release by cultured trophoblast cells have yielded conflicting results. For example, Yagel et al.[9] described a predominantly cytotrophic influence on lymphocyte proliferation by both trophoblast cells and their supernatants, whereas Sanyal et al.[10] observed immunosuppression with similar methods. Discordant observations have also been noted in studies with murine placental extracts presumed to contain distinct molecules that promote suppression or stimulation, depending on their relative concentrations.[11]

Whereas it is possible that the in situ human trophoblast could be both suppressive and stimulatory of maternal immune responses, these contradictory observations might instead be related to differences in the specific methods of prior experiments.[9,10] Retrieval of trophoblast material from pregnancies undergoing elective termination might inadvertantly include samples from gestations destined to develop clinical abnormalities (e.g., intrauterine growth retardation), making inferences regarding normal trophoblast immune function inappropriate. The possibility that some aneuploid pregnancies might be included also exists. In addition, reliance on relatively long-term culture techniques could lead to nontrophoblast cell contamination or even dedifferentiation of trophoblast cells cultured by repeated passage. In the immunologic studies by Yagel et al., trophoblast cell lines were maintained for up to 100 days (by serial in vitro passages at 4- to 8-day intervals).

To avoid these potentially confounding issues and to ensure that the villus samples retrieved for study were associated with genetically and clinically normal pregnancies, we used short-term cultures of karyotypically normal, isolated chorionic villi obtained for prenatal diagnosis from otherwise low-risk patients. Our specific objective was to use this trophoblast source to evaluate

the influence of trophoblast supernatants on selected assays of cellular immune function.

Material and methods

Retrieval of trophoblast supernatants. Chorionic villus tissue was recovered for cytogenetic analysis (after informed consent with a protocol approved by the Institutional Review Board) by either the transabdominal or transcervical route between 8 to 12 weeks' gestation, with sampling methods previously reported.[12] Preparation and culturing of the specimens was accomplished with methods adapted from Simoni et al.[13] and Niazi et al.,[14] designed to minimize the possibility of maternal or nontrophoblast cell contamination.[15] Briefly, recovered villi were meticulously cleaned under an inverted microscope, then reduced to their mesenchymal core by enzyme digestion (trypsin followed by collagenase). This latter step removes the outer syncytiotrophoblast layer along with any adherent nontrophoblast cells (e.g., decidual cells, red blood cells, and macrophages) that remain after the initial dissection. The samples were then centrifuged and resuspended in Chang's growth medium (Hana Biologics, Irvine, Calif.). Primary cultures were refed with fresh media at 24 hours, after which the media were not changed. Cultures were harvested on day 6, at which time there were approximately 2×10^3 cells per culture well. The supernatants were recovered and frozen at −20° C so that the clinical outcome of each pregnancy would be known before inclusion of the sample in the immunologic assays. The supernatants from 55 chorionic villus specimens (obtained between November 1988 and October 1989) from completed, karyotypically and clinically normal pregnancies were selected randomly to be used in the experiments described here. Selected characteristics of the chorionic villus sampling procedures from which these trophoblast supernatant samples were retrieved are summarized in Table I.

Mitogen-stimulated mononuclear cell assays. To determine the effect of trophoblast supernatant on mitogen-induced T-cell transformation, mononuclear cells, isolated from the blood of healthy, nonpregnant adult volunteers and suspended at 2×10^5 cells/ml were cultured for 3 and 4 days with 0.2 μg/ml of phytohemagglutinin (Sigma Chemical Co., St. Louis). Trophoblast supernatant (25% concentration) or an equal volume of control media (growth media that was innoculated into empty culture wells at the initiation of the villus culture) was added at the onset of mitogen stimulation. After an 18-hour tritiated thymidine exposure, cultures were harvested and liquid scintillation counting was performed. Viability testing (by trypan blue exclusion) was >85% in this and all other experiments. The means and SE of all triplicates were calculated and the degree of suppression was expressed as a ratio of the mean counts per minute of trophoblast supernatant experiments over the mean counts per minute of control experiments. Additional assays were also performed with higher and lower concentrations of trophoblast supernatants (1%, 5%, 10%, and 50%) in an attempt to identify a dose-response relationship. T-cell mitogen experiments were repeated with aliquots of heat-inactivated trophoblast supernatants (30 minutes in a 56° C shaking water bath).

One-way, mixed lymphocyte cultures. To confirm that the immunosuppression observed in the mitogen experiments was T-cell specific, 5-day mixed lymphocyte cultures were performed with mononuclear cells from two human lymphocyte antigen–incompatible donors. Responders and stimulators (treated with mitomycin C) were combined in a 5 : 1 ratio (to maximize the detection of immunosuppression). Trophoblast supernatant or control media was added at a 25% concentration to the culture wells at initial coincubation. Cultures were pulsed with tritiated thymidine and then terminated and counted as previously described. Stimulation indexes were calculated for all triplicates after subtraction of background counts derived from autologous combinations. Results were expressed as a ratio of the trophoblast supernatant and control media stimulation index values to quantitate suppression.

Suppressor T-cell inducer assay. To determine whether the observed suppression involved the induction of suppressor T cells by trophoblast supernatant, a two-stage experiment was performed. Initially, mononuclear cells were incubated with 25% trophoblast su-

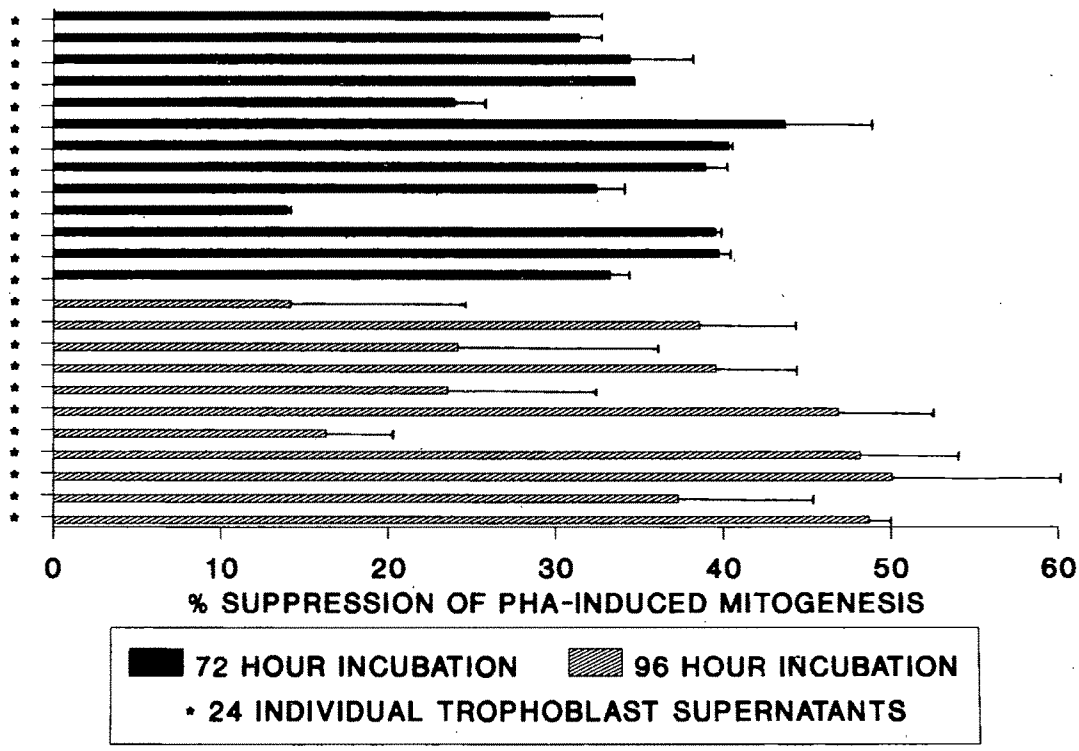

Fig. 1. Suppression of T-cell mitogenesis by trophoblast supernatants. Results from two periods of incubation with 24 different trophoblast supernatant samples. Means and corresponding SEs shown. *PHA*, phytohemagglutinin.

pernatant or media only for 3 days. These two groups of cells were removed by vigorous pipeting, rinsed with media, and then washed and exposed to mitomycin C. In the second stage, both the trophoblast supernatant–treated and control-treated cells (1×10^5 cells/ml) were incubated for 72 additional hours with the same number of fresh, untreated cells and 0.5 μg/ml of phytohemagglutinin. These cultures were pulsed and harvested as previously described. In addition, separate aliquots of the trophoblast supernatant–treated and control-treated cells were analyzed by flow fluorocytometry (Bectin-Dickenson) with antibody labeling to detect any change in the percentage of suppressor $T8^+$ cells (as a consequence of trophoblast supernatant exposure).

Statistical analysis. Group means were analyzed by the two-tailed Student *t* test or analysis of variance. The SEM of each triplicate set is depicted in each figure. A *p* value <0.05 was considered as significant.

Results

Phytohemagglutinin-induced proliferation of T cells was uniformly inhibited in 24 separate trophoblast supernatant experiments with either 3-day or 4-day exposures (Fig. 1). Suppression was observed in all additional supernatants used in these experiments (data not shown). On average, a 34% decrease was observed (range, 14 to 50) and heat inactivation did not alter this finding (mean suppression induced by heat-inactivated trophoblast supernatant = 33%; range, 20 to 44; $n = 10$). Fig. 2 shows a clear dose response, with maximal suppression occurring at the 50% trophoblast supernatant concentration ($p < 0.001$ by Friedman analysis of variance). Performance of one-way mixed lymphocyte cultures in the presence of 25% trophoblast supernatant confirmed immunosuppression in all 10 samples tested (Fig. 3).

An evaluation of suppressor T-cell induction with six individual mononuclear cell donors and eight different trophoblast supernatant samples (known to be suppressive of mitogen-induced proliferation) failed to reveal functional evidence of suppressor T-cell induction (Fig. 4). In fact, moderate enhancement of phytohemagglutinin-induced transformation was noted in most of these experiments. Although an overall increase in the percentage of phenotypic suppressor T cells was observed by fluoresence antibody binding (Table II), this change was also seen in cells exposed to media alone, suggesting that it was a temporal artifact of mononuclear cell culture.

Comment

With the trophoblast source and culture techniques described in this study, trophoblast supernatant con-

*The data shown represent one of the eight trophoblast supernatant samples tested in the suppressor T-cell inducer assay (Fig. 4). Similar results were obtained by incubating the other trophoblast supernatant samples with mononuclear cells from additional donors (results not shown).

†The letter-numeral combinations listed represent the monoclonal antibodies used to identify mononuclear cell subsets.

sistently suppressed mononuclear cell transformation. The ability of the first-trimester trophoblast to inhibit maternal T-cell proliferation by a paracrine mechanism may directly contribute to fetal survival. Many factors produced by the fetoplacental compartment have been reported to be immunosuppressive including chorionic gonadotropin, placental lactogen, pregnancy-associated serum protein A, and others.[16-18] However, before attempting to identify which factor(s) is responsible for local immunoregulation, the appropriateness of the trophoblast source chosen for study should be considered. By using villi retrieved during the first trimester from karyotypically normal, uncomplicated term pregnancies, and by processing these specimens

to exclude nontrophoblast cells, we believe that our in vitro observations closely resemble the paracrine function of the human trophoblast.

The immunosuppression we observed appeared to be directly related to trophoblast supernatant in a dose-dependent fashion. Unlike other studies that have implicated suppressor T-cell induction by trophoblast supernatant as the mechanism for mononuclear cell suppression, we did not confirm this phenomenon. It may be that the relatively short incubation time (72 hours) precluded the detection of suppressor T-cell subpopulations because there was insufficient time for their development. However, Sanyal et al.[10] were able to identify suppressor cell induction with similar techniques. An analysis of their data reveals that only six of the 11 trophoblast supernatant samples tested appeared to induce suppressor T-cell differentiation; a finding that we would interpret as inconclusive.

Future studies should focus on identification of the soluble factor(s) in trophoblast supernatant with immunosuppressive capability. Theoretically, a deficiency of such factors early in pregnancy might be pathologic (e.g., increase the likelihood of miscarriage or predispose a patient to recurrent pregnancy loss). Because chromosomally abnormal gestations exhibit an exaggerated rate of first-trimester fetal wastage, study of aneuploid supernatants identified at the time of chorionic villus sampling might provide a meaningful contrast to the experimental observations associated with normal pregnancies.

We thank Kris Fischer for her invaluable technical assistance in performance of the laboratory assays.

Proliferative and antiproliferative effects of interferon-γ and tumor necrosis factor-α on cell lines derived from cervical and ovarian malignancies

David G. Mutch, MD, L. Stewart Massad, MD, Ming-Shian Kao, MD, and John Leslie Collins, PhD

St. Louis, Missouri

Four human cell lines derived from cervical carcinomas (ME-180, SiHa, HT-3, and MS751) and three human cell lines derived from ovarian carcinomas (SK-OV-3, Caov-3, and NIH:OVCAR-3) were analyzed in vitro to determine the effect of recombinant interferon-γ and recombinant human tumor necrosis factor-α on cell growth and survival. The effects of interferon-γ, tumor necrosis factor-α, and both interferon-γ and tumor necrosis factor-α on cell growth were measured after 24 and 72 hours of incubation by the incorporation of chromium 51. The results of this analysis showed that all seven cell lines were resistant to the antiproliferative action of tumor necrosis factor-α, that the growth of most cell lines was inhibited by interferon-γ by 72 hours of incubation, and that after 72 hours of incubation all cell lines demonstrated a synergistic antiproliferative response to the combination of interferon-γ and tumor necrosis factor-α. However, the effects of these cytokines on cell growth were found to differ among cell lines and varied with the concentration and the duration of incubation. The growth of one cell line (Caov-3) was stimulated by both tumor necrosis factor-α and interferon-γ. These results suggest that the clinical effects of these cytokines on the growth of gynecologic cancers may be more complex than previously supposed. (Am J Obstet Gynecol 1990;163:1920-4.)

Key words: Tumor necrosis factor-α, interferon-γ, cell growth, gynecologic malignancy

Cytokines are proteins, secreted by macrophages and lymphocytes, that are known to modulate the growth of various tissues. Recent advances in recombinant deoxyribonucleic acid technology have made possible the synthesis of large quantities of cytokines in pure form, allowing study of the effects of these peptides individually on a variety of cell types. The cytokines tumor necrosis factor-α and interferon-γ have shown in vitro antiproliferative effects on cell lines derived from gynecologic malignancies.[1-8] The combination of these two cytokines often acts synergistically to inhibit cell growth in vitro.[1-5] The antiproliferative effects of tumor necrosis factor-α and interferon-γ in vitro have prompted clinical studies of these cytokines as anticancer agents. Unfortunately, few clinical responses have been noted.[9-15]

The discrepancy between the clinical and in vitro responses of gynecologic cancer cells to these cytokines suggests that the actions of tumor necrosis factor-α or interferon-γ on cancer cells may be more complex than previously supposed. To evaluate the potential variability of responses to tumor necrosis factor-α and interferon-γ, we investigated the effects of these two cytokines on the growth of seven arbitrarily selected cell lines derived from human cervical and ovarian carcinomas.

Material and methods

Cell lines. ME-180, SiHa, HT-3, and MS751 are independent cell lines originally derived from human cervical carcinomas. SK-OV-3, Caov-3, and NIH:OVCAR-3 are independent cell lines originally derived from human ovarian carcinomas. All cell lines were obtained from the American Type Culture Collection (Rockville, Md.) and were maintained as exponentially growing cultures. All cell lines except HT-3 and NIH:OVCAR-3 were grown in Dulbecco's modified Eagle's medium supplemented with 30 mg/ml L-glutamine (Sigma Chemical Co., St. Louis), 450 U/ml penicillin (Sigma), 40μg/ml streptomycin (Sigma), and 10% fetal bovine serum (HyClone Laboratories, Logan, Utah). HT-3 cells were grown in McCoy's medium containing the same supplements as Dulbecco's modified Eagle medium. NIH:OVCAR-3 cells were grown in RPMI-1640 medium containing the

same supplements as Dulbecco's modified Eagle medium with an additional 10 μg/ml recombinant human insulin (Eli Lilly & Co., Indianapolis). NIH:OVCAR-3 cells were grown at 37° C in a humidified atmosphere of 5% carbon dioxide and 95% air. All other cells were grown at 37° C in a humidified atmosphere of 10% carbon dioxide and 90% air.

Cytokines. Recombinant human interferon-γ (2.5×10^7 U/mg) was obtained from Genzyme (Boston) and was reconstituted with Dulbecco's modified Eagle medium (10^5 U/ml). Recombinant human tumor necrosis factor-α (2×10^7 U/ml, Genzyme) also was reconstituted with Dulbecco's modified Eagle medium (10^4 U/ml). Both cytokines were stored at −70° C until use, when they were diluted in the appropriate medium used for the routine growth of cells before use in the assay of cell growth.

Assay of cell growth by incorporation of chromium 51. Cells were plated at time 0 in 96-well microtiter plates at 2×10^3 cells per well in 50 μl of the medium used for the routine growth of cells and incubated under the usual growth conditions. At 24 hours, 50 μl of interferon-γ or control medium and 50 μl of tumor necrosis factor-α or control medium were added to each well. Cells then were incubated for an additional 24 to 72 hours under usual growth conditons, when media were removed for labeling. At specified times after the addition of cytokines, each well received 30 μl of ^{51}Cr (50 μCi/ml, New England Nuclear/DuPont, Boston) in RPMI-1640 medium containing 3 gm/ml bovine serum albumin (Sigma). Plates were incubated 3 hours in a humidified atmosphere of 5% carbon dioxide at 37° C. Each well was washed four times with 100 μl Dulbecco's modified Eagle medium to remove unincorporated ^{51}Cr. Cells were lysed by the addition of 150 μl of distilled water for 15 to 20 minutes. The microtiter plates were shaken to complete lysis, then centrifuged 10 minutes. From each well, 75 μl of supernatant was removed and counted in a γ-counter. Six replicate wells containing no interferon-γ or tumor necrosis factor-α were counted from each plate. The percent growth that resulted from incubation with cytokines was calculated by the following formula: Percent growth = (cpm ^{51}Cr incorporated by treated cells/cpm ^{51}Cr incorporated by control cells) × 100.

Statistical analysis. The high and low values from each group of six wells were dropped. The means of the remaining four wells were compared with Student's *t* test. The results presented are representative of multiple experiments. Synergy between tumor necrosis factor-α and interferon-γ was assumed to exist if one or both of these agents had no significant effect on cell growth and the percent growth in the presence of their combination was significantly different from that in the presence of either cytokine alone. When both agents significantly altered growth when used alone, synergy was assessed by the construction of isobolograms.[16]

Results

Effects on cell growth of 24 hours of incubation with interferon-γ and tumor necrosis factor-α. We have previously shown that ME-180, MS751, SiHa, HT-3, SK-OV-3, NIH:OVCAR-3, and Caov-3 are all resistant to lysis by tumor necrosis factor-α and interferon-γ when measured in a 24-hour ^{51}Cr release assay.[17,18] These cytokines have also been shown to either increase or decrease the growth of different cell lines in vitro.[1-8] To determine the effects of tumor necrosis factor-α and interferon-γ on cell growth, cells were incubated with various concentrations of tumor necrosis factor-α, interferon-γ, or tumor necrosis factor-α and interferon-γ. After 24 hours of incubation, cell growth was measured by the incorporation of ^{51}Cr. The growth of treated cells was expressed as a percent of untreated control cells.

As shown in Table I, tumor necrosis factor-α did not affect the growth of any of the cell lines except that of Caov-3, which was significantly increased in the presence of tumor necrosis factor-α at concentrations of 10 and 100 U/ml. Interferon-γ at a concentration of 10 and 100 U/ml also increased the growth of the cell line Caov-3. Contrary to its growth-stimulatory effect on Caov-3 cells, interferon-γ inhibited the growth of ME-180, MS751, and HT-3 cells.

As shown in Table I, the combination of tumor necrosis factor-α and interferon-γ at 100 U/ml was synergistic in inhibiting the growth of ME-180, SiHa, HT-3, and SK-OV-3 cells. Although the growth of MS751 cells was inhibited by interferon-γ alone, the combination of tumor necrosis factor-α and interferon-γ appeared to be antagonistic (i.e., the combination did not inhibit growth). The combination of tumor necrosis factor-α and interferon-γ did not increase the proliferative effects that these two cytokines elicited individually in Caov-3 cells.

Effects on cell growth of 72 hours of incubation with of tumor necrosis factor-α and interferon-γ. To determine whether periods of incubation with tumor necrosis factor-α or interferon-γ might elicit growth responses that were quantitatively or qualitatively different from those observed at 24 hours, cells were incubated with tumor necrosis factor-α, interferon-γ, or tumor necrosis factor-α and interferon-γ for 72 hours. The growth of treated cells was compared with that of untreated cells as described above. As shown in Table II, 72 hours of incubation with cytokines resulted primarily in quantitative changes in the growth of cells compared with 24 hours of incubation.

As with 24 hours of treatment, the treatment of cells with tumor necrosis factor-α for 72 hours did not sig-

nificantly inhibit the growth of any cell line, and it accelerated the growth of Caov-3 cells (Table II). Whereas treatment of NIH:OVCAR-3 cells with tumor necrosis factor-α for 24 hours had no effect, treatment for 72 hours with 10 U/ml increased the growth of these cells (Table II). The magnitude of the response of cells to interferon-γ was increased by treatment for 72 hours compared with 24 hours. Thus, extending the duration of treatment with interferon-γ from 24 to 72 hours resulted in greater growth inhibition of the cell lines ME-180, MS751, SiHa, and HT-3. In addition, the growth of two cell lines (SK-OV-3 and NIH:OVCAR-3) that was not affected by 24 hours of exposure to interferon-γ was significantly decreased when treated with 100 U/ml for 72 hours (Table II). Although treatment with interferon-γ for 24 hours increased the growth of Caov-3 cells, this response did not occur when the duration of incubation was increased to 72 hours (Table II).

As shown in Table II, synergistic growth inhibition by the combination of interferon-γ and tumor necrosis factor-α was seen in all cell lines when cells were treated with 100 U/ml of tumor necrosis factor-α and 100 U/ml of interferon-γ for 72 hours. This was true even for Caov-3 cells, which continued to show significant growth stimulation at lower concentrations (i.e., at 1 and 10 U/ml) of tumor necrosis factor-α and interferon-γ.

Although the effects of tumor necrosis factor-α, interferon-γ, or tumor necrosis factor-α and interferon-γ on cell growth were found to differ among the seven cell lines (Tables I and II), these differences were not related to inherent differences in the growth rates of the cell lines. The doubling times of all cell lines, except Caov-3, varied from 21 to 34 hours; for some cell lines that differ greatly in their response to these cytokines, there was no difference in their doubling times (data not shown).

Comment

Several authors have reported the effects of tumor necrosis factor-α and interferon-γ on the in vitro

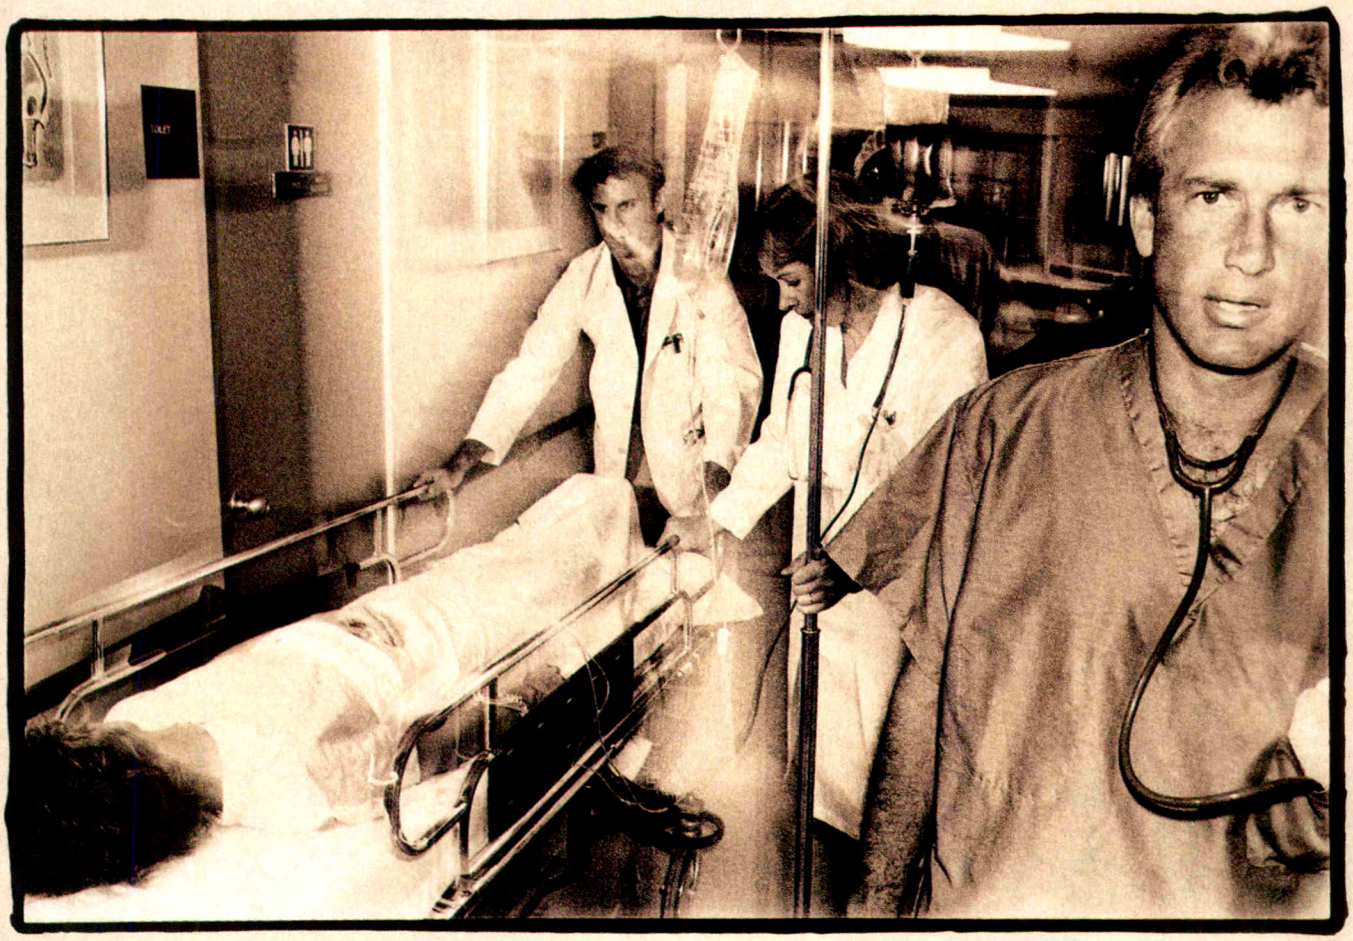
growth of cell lines derived from cervical and ovarian malignancies.[1-8] These reports have emphasized the inhibitory actions of these cytokines, but the results of early clinical trials with these cytokines in the treatment of cancer have yielded few responses.[9-15] Our findings suggest several possible explanations for this in vivo resistance to tumor necrosis factor-α and interferon-γ.

The results presented in our report show that the antiproliferative effects of tumor necrosis factor-α and interferon-γ depend on the duration of exposure of cells to these cytokines. After 24 hours of incubation, only two of seven cell lines showed inhibition of growth by tumor necrosis factor-α (Table I). Interferon-γ inhibited the growth of five of seven cell lines at 24 hours, but the magnitude of inhibition did not become pronounced until cells were incubated with interferon-γ for 72 hours (Table II). Phase I clinical trials have shown that although significant serum concentrations of tumor necrosis factor-α and interferon-γ are achieved shortly after their administration, the levels of these cytokines decline rapidly and are rarely measurable in serum after 24 hours.[9-15] Therefore clinical efficacy may require sustained administration.

In addition to the duration of exposure to tumor necrosis factor-α and interferon-γ, our results also suggest that growth inhibition may be dose dependent. In the cell lines tested, growth inhibition rarely occurred at cytokine concentrations of 1 to 10 U/ml and only became significant at 100 U/ml. The majority of reports on the in vitro antiproliferative effects of these agents have used cytokine concentrations >10,000 U/ml.[1-8] Clinical studies have shown that levels of tumor necrosis factor-α and interferon-γ that can be sustained for several hours rarely exceed 100 U/ml.[9-14] If these cytokines only inhibit cell growth in vivo when their concentrations approximate 100 U/ml, then clinical control of tumors may require the development of techniques for the regional delivery of higher cytokine concentrations.

To date, most studies of the growth effects of tumor necrosis factor-α and interferon-γ on human cancer cells have reported on only a small number of cervical and ovarian cell lines.[1-8] Our data, based on a series of seven arbitrarily selected cell lines derived from human cervical and ovarian carcinomas, show that there is considerable heterogeneity in the responses of these cell lines to tumor necrosis factor-α and interferon-γ (Tables I and II). We found that most cell lines are resistant to growth inhibition by tumor necrosis factor-α at pharmacologic concentrations and that cell lines vary substantially in their sensitivity to interferon-γ. Caov-3 cells actually grew more rapidly in the presence of either tumor necrosis factor-α or interferon-γ. Clinically, the incidence of resistance to growth inhibition by tumor necrosis factor-α may be high, and some tumors may respond to exposure to tumor necrosis factor-α or interferon-γ with accelerated growth, as the cell line Caov-3 did in this study.

Finally, it should be noted that growth inhibition and cell lysis are not synonymous. Many assays that measure the effects of cytokines or other anticancer agents on cells compare the relative numbers of treated and untreated cells after some period of incubation. If the number of treated cells is less than the number of untreated cells, it cannot be known whether the decrease in the number of treated cells is a result of cytostasis or cytolysis. This is true regardless of how cells are enumerated and is particularly problematic with extended periods of treatment (i.e., when the period of incubation is sufficient to permit an increase in the number of untreated cells). We have shown previously that exposure of these cells to tumor necrosis factor-α or interferon-γ for up to 24 hours does not result in lysis,[17,18] and the assay technique used in this and most other studies cannot distinguish cytolysis from cytostasis.[1-3, 5-8] If in vivo, as in vitro, the effects of tumor necrosis factor-α and interferon-γ are only cytostatic, slow-growing tumors may appear unresponsive to these agents. Furthermore, the cytostatic effects of these agents may not persist after the cytokines have been cleared from the circulation, and tumors, although briefly growth inhibited, may then resume growth.



Our data confirm several reports that have noted the antiproliferative synergy of the combination of interferon-γ and tumor necrosis factor-α.[1-5] Others have proposed that such synergy may result from interferon–induced upregulation of cell surface receptors for tumor necrosis factor-α,[19] although the number of surface receptors specific for tumor necrosis factor-α does not correlate with sensitivity to tumor necrosis factor-α.[20] The results presented herein show that the addition of interferon-γ can inhibit cell growth, apparently independently of the addition of tumor necrosis factor-α. A number of cell lines of diverse histologic type have been shown to secrete tumor necrosis factor-α constitutively.[7, 21] In addition, interferon-γ has been shown to stimulate the production of tumor necrosis factor-α in monocytes.[22] To rule out the possibility that the addition of interferon-γ induces the secretion of tumor necrosis factor-α, supernatant fluids from ME-180 cells incubated with and without interferon-γ were analyzed for the presence of tumor necrosis factor-α.[23] The results of this analysis showed that ME-180 cells do not secrete tumor necrosis factor-α into the media even when interferon-γ was added (data not shown). It thus seems unlikely that interferon-γ inhibits cell growth through a mechanism involving tumor necrosis factor-α.

The results of this study suggest that the mechanism of the observed synergistic antiproliferative effect of tumor necrosis factor-α and interferon-γ may be more

complex than the simple increase in the number of tumor necrosis factor-α receptors or induction of tumor necrosis factor-α secretion by interferon-γ. Regardless of the mechanism of synergy between tumor necrosis factor-α and interferon-γ in inhibiting the growth of carcinoma cell lines, our results suggest that a combination therapy with tumor necrosis factor-α and interferon-γ would improve the efficacy of these cytokines as anticancer agents.

CURRENT PROBLEMS IN OBSTETRICS, GYNECOLOGY AND FERTILITY

Editor-in-Chief: **Robert L. Barbieri, MD**
State University of New York at Stony Brook

Current Problems in Obstetrics, Gynecology and Fertility brings you the authoritative, practical information you need to stay current in your specialty and to provide the best possible care to patients.

- Each bimonthly issue provides in-depth, monograph-length coverage (40-60 pages) of a clinical topic of vital interest to practitioners today.
- Topics are selected for relevance to your daily practice: preconceptual counseling, infertility, endocrine problems, high-risk obstetrics, diagnosis and treatment of primary and secondary amenorrhea, pediatric and adolescent gynecology, and more.
- Authors are selected for their expertise; you'll benefit from their balanced perspective on the topic and their wealth of clinical experience.
- Each article is extensively referenced, saving you hours of library research and serving as a long-term, practical resource.

INDICATIONS AND USAGE

UNASYN is indicated for the treatment of infections due to susceptible strains of the designated microorganisms in the conditions listed below.

Skin and Skin Structure Infections caused by beta-lactamase producing strains of *Staphylococcus aureus*, *Escherichia coli*,* *Klebsiella* spp.* (including *K. pneumoniae**), *Proteus mirabilis*,* *Bacteroides fragilis*,* *Enterobacter* spp.,* and *Acinetobacter calcoaceticus*.*

Intra-Abdominal Infections caused by beta-lactamase producing strains of *Escherichia coli*, *Klebsiella* spp. (including *K. pneumoniae**), *Bacteroides* spp. (including *B. fragilis*), and *Enterobacter* spp.*

Gynecological Infections caused by beta-lactamase producing strains of *Escherichia coli*,* and *Bacteroides* spp.* (including *B. fragilis**).

*Efficacy for this organism in this organ system was studied in fewer than 10 infections.

While UNASYN* (ampicillin sodium/sulbactam sodium) is indicated only for the conditions listed above, infections caused by ampicillin-susceptible organisms are also amenable to treatment with UNASYN due to its ampicillin content. Therefore, mixed infections caused by ampicillin-susceptible organisms and beta-lactamase producing organisms susceptible to UNASYN should not require the addition of another antibiotic.

CONTRAINDICATIONS

The use of UNASYN is contraindicated in individuals with a history of hypersensitivity reactions to any of the penicillins.

WARNINGS

SERIOUS AND OCCASIONALLY FATAL HYPERSENSITIVITY (ANAPHYLACTIC) REACTIONS HAVE BEEN REPORTED IN PATIENTS ON PENICILLIN THERAPY. THESE REACTIONS ARE MORE APT TO OCCUR IN INDIVIDUALS WITH A HISTORY OF PENICILLIN HYPERSENSITIVITY AND/OR HYPERSENSITIVITY REACTIONS TO MULTIPLE ALLERGENS. THERE HAVE BEEN INDIVIDUALS WITH A HISTORY OF PENICILLIN HYPERSENSITIVITY WHO HAVE EXPERIENCED SEVERE REACTIONS WHEN TREATED WITH CEPHALOSPORINS. BEFORE THERAPY WITH A PENICILLIN, CAREFUL INQUIRY SHOULD BE MADE CONCERNING PREVIOUS HYPERSENSITIVITY REACTIONS TO PENICILLINS, CEPHALOSPORINS, AND OTHER ALLERGENS. IF AN ALLERGIC REACTION OCCURS, UNASYN SHOULD BE DISCONTINUED AND THE APPROPRIATE THERAPY INSTITUTED.

SERIOUS ANAPHYLACTOID REACTIONS REQUIRE IMMEDIATE EMERGENCY TREATMENT WITH EPINEPHRINE. OXYGEN, INTRAVENOUS STEROIDS, AND AIRWAY MANAGEMENT, INCLUDING INTUBATION, SHOULD ALSO BE ADMINISTERED AS INDICATED.

PRECAUTIONS

General: A high percentage of patients with mononucleosis who receive ampicillin develop a skin rash. Thus, ampicillin class antibiotics should not be administered to patients with mononucleosis. In patients treated with UNASYN the possibility of superinfections with mycotic or bacterial pathogens should be kept in mind during therapy. If superinfections occur (usually involving *Pseudomonas* or *Candida*), the drug should be discontinued and/or appropriate therapy instituted.

Drug Interactions: Probenecid decreases the renal tubular secretion of ampicillin and sulbactam. Concurrent use of probenecid with UNASYN may result in increased and prolonged blood levels of ampicillin and sulbactam. The concurrent administration of allopurinol and ampicillin increases substantially the incidence of rashes in patients receiving both drugs as compared to patients receiving ampicillin alone. It is not known whether this potentiation of ampicillin rashes is due to allopurinol or the hyperuricemia present in these patients. There are no data with UNASYN and allopurinol administered concurrently. UNASYN and aminoglycosides should not be reconstituted together due to the *in vitro* inactivation of aminoglycosides by the ampicillin component of UNASYN.

Drug/Laboratory Test Interactions: Administration of UNASYN will result in high urine concentrations of ampicillin. High urine concentrations of ampicillin may result in false positive reactions when testing for the presence of glucose in urine using Clinitest™, Benedict's Solution or Fehling's Solution. It is recommended that glucose tests based on enzymatic glucose oxidase reactions (such as Clinistix™ or Testape™) be used. Following administration of ampicillin to pregnant women, a transient decrease in plasma concentration of total conjugated estriol, estriol-glucuronide, conjugated estrone, and estradiol has been noted. This effect may also occur with UNASYN.

Carcinogenesis, Mutagenesis, Impairment of Fertility: Long-term studies in animals have not been performed to evaluate carcinogenic or mutagenic potential.

Pregnancy

Pregnancy Category B: Reproduction studies have been performed in mice, rats, and rabbits at doses up to ten (10) times the human dose and have revealed no evidence of impaired fertility or harm to the fetus due to UNASYN. There are, however, no adequate and well controlled studies in pregnant women. Because animal reproduction studies are not always predictive of human response, this drug should be used during pregnancy only if clearly needed. (See—Drug/Laboratory Test Interactions.)

Labor and Delivery: Studies in guinea pigs have shown that intravenous administration of ampicillin decreased the uterine tone, frequency of contractions, height of contractions, and duration of contractions. However, it is not known whether the use of UNASYN in humans during labor or delivery has immediate or delayed adverse effects on the fetus, prolongs the duration of labor, or increases the likelihood that forceps delivery or other obstetrical intervention or resuscitation of the newborn will be necessary.

Nursing Mothers: Low concentrations of ampicillin and sulbactam are excreted in the milk; therefore, caution should be exercised when UNASYN is administered to a nursing woman.

Pediatric Use: The efficacy and safety of UNASYN have not been established in infants and children under the age of 1.2.

ADVERSE REACTIONS

UNASYN is generally well tolerated. The following adverse reactions have been reported:

Local Adverse Reactions

Pain at IM injection site—16% Pain at IV injection site—3%
Thrombophlebitis—3%

Systemic Adverse Reactions

The most frequently reported adverse reactions were diarrhea in 3% of the patients and rash in less than 2% of the patients.

Additional systemic reactions reported in less than 1% of the patients were: itching, nausea, vomiting, candidiasis, fatigue, malaise, headache, chest pain, flatulence, abdominal distension, glossitis, urine retention, dysuria, edema, facial swelling, erythema, chills, tightness in throat, substernal pain, epistaxis and mucosal bleeding.

Adverse Laboratory Changes

Adverse laboratory changes without regard to drug relationship that were reported during clinical trials were:

Hepatic: Increased AST (SGOT), ALT (SGPT), alkaline phosphatase, and LDH.

Hematologic: Decreased hemoglobin, hematocrit, RBC, WBC, neutrophils, lymphocytes, platelets and increased lymphocytes, monocytes, basophils, eosinophils, and platelets.

Blood Chemistry: Decreased serum albumin and total proteins.

Renal: Increased BUN and creatinine.

Urinalysis: Presence of RBC's and hyaline casts in urine.

The following adverse reactions have been reported with ampicillin-class antibiotics and can also occur with UNASYN:

Gastrointestinal: Gastritis, stomatitis, black hairy tongue, enterocolitis and pseudomembranous colitis.

Hypersensitivity Reactions: Urticaria, erythema multiforme, and an occasional case of exfoliative dermatitis have been reported. These reactions may be controlled with antihistamines and, if necessary, systemic corticosteroids. Whenever such reactions occur, the drug should be discontinued, unless the opinion of the physician dictates otherwise. Serious and occasional fatal hypersensitivity (anaphylactic) reactions can occur with a penicillin (see WARNINGS).

Hematologic: In addition to the adverse laboratory changes listed above for UNASYN, agranulocytosis has been reported during therapy with penicillins. All of these reactions are usually reversible on discontinuation of therapy and are believed to be hypersensitivity phenomena.

38A

"I used to think only <u>two</u> things in life were certain."

Nothing comes closer to 100% activity against anaerobes in vitro. It's a fact. Studies have proved no other antibiotic superior to UNASYN in overall antianaerobic activity.[1-10] Not clindamycin. Not metronidazole. Nothing.

And that's nothing to overlook—given the importance of anaerobes in today's mixed infections.

Though clinical results may not always mirror those obtained in vitro, there's a world of confidence in choosing UNASYN for presumptive therapy of the mixed infections* you see every day.

PERSONALIZED LIBRARY CASES

Protect your personal copies of
AMERICAN JOURNAL OF OBSTETRICS AND GYNECOLOGY
in custom made, titled library cases.

Constructed of durable, reinforced binder's board covered in a rich simulated leather, each is designed to hold an entire year's issues. The Journal name is stamped in gold leaf, making the cases attractive additions to any decor, whether on your bookshelf, desk or any location in your home or office.

Only $7.95 each: 3 for $21.95; 6 for $39.95, and $1 per unit postage and handling ($2.50 per unit outside the U.S.A.). U.S. funds only.

To charge your order using American Express, Visa, MasterCard or Diners Club, call toll-free: 1-800-972-5858.

INDICATIONS AND USAGE

UNASYN is indicated for the treatment of infections due to susceptible strains of the designated microorganisms in the conditions listed below.

Skin and Skin Structure Infections caused by beta-lactamase producing strains of *Staphylococcus aureus*, *Escherichia coli*,* *Klebsiella* spp.* (including *K. pneumoniae**), *Proteus mirabilis*,* *Bacteroides fragilis*,* *Enterobacter* spp.*, and *Acinetobacter calcoaceticus*.*

Intra-Abdominal Infections caused by beta-lactamase producing strains of *Escherichia coli*, *Klebsiella* spp. (including *K. pneumoniae**), *Bacteroides* spp. (including *B. fragilis*), and *Enterobacter* spp.*

Gynecological Infections caused by beta-lactamase producing strains of *Escherichia coli*,* and *Bacteroides* spp.* (including *B. fragilis**)

*Efficacy for this organism in this organ system was studied in fewer than 10 infections.

While UNASYN* (ampicillin sodium/sulbactam sodium) is indicated only for the conditions listed above, infections caused by ampicillin-susceptible organisms are also amenable to treatment with UNASYN due to its ampicillin content. Therefore, mixed infections caused by ampicillin-susceptible organisms and beta-lactamase producing organisms susceptible to UNASYN should not require the addition of another antibiotic.

CONTRAINDICATIONS

The use of UNASYN is contraindicated in individuals with a history of hypersensitivity reactions to any of the penicillins.

WARNINGS

SERIOUS AND OCCASIONALLY FATAL HYPERSENSITIVITY (ANAPHYLACTIC) REACTIONS HAVE BEEN REPORTED IN PATIENTS ON PENICILLIN THERAPY. THESE REACTIONS ARE MORE APT TO OCCUR IN INDIVIDUALS WITH A HISTORY OF PENICILLIN HYPERSENSITIVITY AND/OR HYPERSENSITIVITY REACTIONS TO MULTIPLE ALLERGENS. THERE HAVE BEEN INDIVIDUALS WITH A HISTORY OF PENICILLIN HYPERSENSITIVITY WHO HAVE EXPERIENCED SEVERE REACTIONS WHEN TREATED WITH CEPHALOSPORINS. BEFORE THERAPY WITH A PENICILLIN, CAREFUL INQUIRY SHOULD BE MADE CONCERNING PREVIOUS HYPERSENSITIVITY REACTIONS TO PENICILLINS, CEPHALOSPORINS, AND OTHER ALLERGENS. IF AN ALLERGIC REACTION OCCURS, UNASYN SHOULD BE DISCONTINUED AND THE APPROPRIATE THERAPY INSTITUTED.

SERIOUS ANAPHYLACTOID REACTIONS REQUIRE IMMEDIATE EMERGENCY TREATMENT WITH EPINEPHRINE. OXYGEN, INTRAVENOUS STEROIDS, AND AIRWAY MANAGEMENT, INCLUDING INTUBATION, SHOULD ALSO BE ADMINISTERED AS INDICATED.

PRECAUTIONS

General: A high percentage of patients with mononucleosis who receive ampicillin develop a skin rash. Thus, ampicillin class antibiotics should not be administered to patients with mononucleosis. In patients treated with UNASYN, the possibility of superinfections with mycotic or bacterial pathogens should be kept in mind during therapy. If superinfections occur (usually involving *Pseudomonas* or *Candida*), the drug should be discontinued and/or appropriate therapy instituted.

Drug Interactions: Probenecid decreases the renal tubular secretion of ampicillin and sulbactam. Concurrent use of probenecid with UNASYN may result in increased and prolonged blood levels of ampicillin and sulbactam. The concurrent administration of allopurinol and ampicillin increases substantially the incidence of rashes in patients receiving both drugs as compared to patients receiving ampicillin alone. It is not known whether this potentiation of ampicillin rashes is due to allopurinol or the hyperuricemia present in these patients. There are no data with UNASYN and allopurinol administered concurrently. UNASYN and aminoglycosides should not be reconstituted together due to the *in vitro* inactivation of aminoglycosides by the ampicillin component of UNASYN.

Drug/Laboratory Test Interactions: Administration of UNASYN will result in high urine concentrations of ampicillin. High urine concentrations of ampicillin may result in false positive reactions when testing for the presence of glucose in urine using Clinitest.® Benedict's Solution or Fehling's Solution. It is recommended that glucose tests based on enzymatic glucose oxidase reactions (such as Clinistix.® or Testape.®) be used. Following administration of ampicillin to pregnant women, a transient decrease in plasma concentration of total conjugated estriol, estriolglucuronide, conjugated estrone, and estradiol has been noted. This effect may also occur with UNASYN.

Carcinogenesis, Mutagenesis, Impairment of Fertility: Long-term studies in animals have not been performed to evaluate carcinogenic or mutagenic potential.

Pregnancy

Pregnancy Category B: Reproduction studies have been performed in mice, rats, and rabbits at doses up to ten (10) times the human dose and have revealed no evidence of impaired fertility or harm to the fetus due to UNASYN. There are, however, no adequate and well controlled studies in pregnant women. Because animal reproduction studies are not always predictive of human response, this drug should be used during pregnancy only if clearly needed. (See—Drug/Laboratory Test Interactions.)

Labor and Delivery: Studies in guinea pigs have shown that intravenous administration of ampicillin decreased the uterine tone, frequency of contractions, height of contractions, and duration of contractions. However, it is not known whether the use of UNASYN in humans during labor or delivery has immediate or delayed adverse effects on the fetus, prolongs the duration of labor, or increases the likelihood that forceps delivery or other obstetrical intervention or resuscitation of the newborn will be necessary.

Nursing Mothers: Low concentrations of ampicillin and sulbactam are excreted in the milk; therefore, caution should be exercised when UNASYN is administered to a nursing woman.

Pediatric Use: The efficacy and safety of UNASYN have not been established in infants and children under the age of 12.

ADVERSE REACTIONS

UNASYN is generally well tolerated. The following adverse reactions have been reported:

Local Adverse Reactions

Pain at IM injection site—16% Pain at IV injection site—3%
Thrombophlebitis—3%

Systemic Adverse Reactions

The most frequently reported adverse reactions were diarrhea in 3% of the patients and rash in less than 2% of the patients.

Additional systemic reactions reported in less than 1% of the patients were: itching, nausea, vomiting, candidiasis, fatigue, malaise, headache, chest pain, flatulence, abdominal distension, glossitis, urine retention, dysuria, edema, facial swelling, erythema, chills, tightness in throat, substernal pain, epistaxis and mucosal bleeding.

Adverse Laboratory Changes

Adverse laboratory changes without regard to drug relationship that were reported during clinical trials were:

Hepatic: Increased AST (SGOT), ALT (SGPT), alkaline phosphatase, and LDH.

Hematologic: Decreased hemoglobin, hematocrit, RBC, WBC, neutrophils, lymphocytes, platelets and increased lymphocytes, monocytes, basophils, eosinophils, and platelets.

Blood Chemistry: Decreased serum albumin and total proteins.

Renal: Increased BUN and creatinine.

Urinalysis: Presence of RBC's and hyaline casts in urine.

The following adverse reactions have been reported with ampicillin-class antibiotics and can also occur with UNASYN:

Gastrointestinal: Gastritis, stomatitis, black "hairy" tongue, enterocolitis and pseudomembranous colitis.

Hypersensitivity Reactions: Urticaria, erythema multiforme, and an occasional case of exfoliative dermatitis have been reported. These reactions may be controlled with antihistamines and, if necessary, systemic corticosteroids. Whenever such reactions occur, the drug should be discontinued unless the opinion of the physician dictates otherwise. Serious and occasional fatal hypersensitivity (anaphylactic) reactions can occur with a penicillin (see WARNINGS).

Hematologic: In addition to the adverse laboratory changes listed above for UNASYN, agranulocytosis has been reported during therapy with penicillins. All of these reactions are usually reversible on discontinuation of therapy and are believed to be hypersensitivity phenomena.

INDICATIONS AND USAGE

UNASYN is indicated for the treatment of infections due to susceptible strains of the designated microorganisms in the conditions listed below.

Skin and Skin Structure Infections caused by beta-lactamase producing

"We need gold-standard results that don't cost a fortune."

Lower antibiotic costs without lowering your standards. UNASYN costs at least 40% less per day than clindamycin/gentamicin or cefoxitin.[11] Yet UNASYN is at least as effective in a variety of mixed infections.*[3,12-19]

And in some studies versus combination therapy, patients treated with UNASYN spent fewer days in the hospital.[3,16,17]

So, look to UNASYN for highly effective, highly affordable therapy in mixed infections* every day.

Smart, current, in-depth, tough, unique, charismatic, authoritative, handy, relevant, lucid, thorough, convenient, detailed, pithy, top-notch, helpful, sagacious, indispensible, comprehensive, thought-provoking, timely, incisive, straightforward, lively, astute, invaluable, concise, fact-packed, and one-of-a-kind.

Okay. So we went a little overboard. But we could go on and on about the *Year Book of Infertility.* We could gush about how it gives you abstracts of the 310 most important articles from the past year. And we could carry on about our distinguished editors who comment on the significance and clinical application of the abstracts.

But let's be honest, you've probably seen other publishers use these same words to describe their products. And no list of adjectives can really convey a book's usefulness and value. *You've got to evaluate it for yourself.*

That's why we're offering you this no-risk, no-obligation, 30-day, free trial of the *Year Book of Infertility.* Just give us a call or drop this coupon in the mail and we'll send you a free examination copy. Put it to work for a month, and if you're not completely satisfied, just send it back and owe nothing.

We are confident, however, that you'll want to add a few adjectives of your own to this list—extraordinary, delectable, and revolutionary are still available.

This Year Book is published annually. For the convenience of our customers, Mosby-Year Book enters each purchaser as a subscriber to future volumes and sends annual announcements approximately 2 months before publication. The new volume will be shipped upon publication unless you complete and return the announcement requesting cancellation within the time indicated. You may cancel your subscription at any time. Each new volume may be examined for 30 days, and may be returned for full credit. Return postage is guaranteed.

WE HAVE A POINT TO MAKE.

SO LITTLE CAN DO SO MUCH.

The Smart Start

OVCON® 35

(norethindrone [0.4 mg] and ethinyl estradiol [0.035 mg]) tablets

Ovcon® 35 offers your patients contraception, with the lowest norethindrone dose of any combination OC. Low incidence of both androgenic side effects[1] and breakthrough bleeding.[2]

Ovcon 35 has a unique estrogen/progestogen ratio. And remember—Ovcon 35 has no generic equivalent.

Amazing how so little can do so much. Our point. Exactly.

OVCON® 35

(norethindrone [0.4 mg] and ethinyl estradiol [0.035 mg]) tablets

Indications and Usage: Ovcon is indicated for the prevention of pregnancy. Some combination products containing 35 mcg or less of ethinyl estradiol report slightly higher pregnancy rates than are reported for the higher dose combination products.

Dose-related Risk of Thromboembolism from Oral Contraceptives: Two studies have shown a positive association between the dose of estrogens in oral contraceptives and the risk of thromboembolism. For this reason, it is prudent and in keeping with good principles of therapeutics to minimize exposure to estrogen. The oral contraceptive product prescribed for any given patient should be that product which contains the least amount of estrogen that is compatible with an acceptable pregnancy rate and patient acceptance. It is recommended that new acceptors of oral contraceptives be started on preparations containing 50 mcg or less of estrogen.

Contraindications: Oral contraceptives should not be used in women with any of the following conditions: 1) Thrombophlebitis or thromboembolic disorders. 2) A past history of deep vein thrombophlebitis or thromboembolic disorders. 3) Cerebral vascular or coronary artery disease. 4) Known or suspected carcinoma of the breast. 5) Known or suspected estrogen dependent neoplasia. 6) Undiagnosed abnormal genital bleeding. 7) Known or suspected pregnancy. 8) Benign or malignant liver tumor which developed during the use of oral contraceptive or other estrogen-containing products.

Warnings:

Cigarette smoking increases the risk of serious cardiovascular side effects from oral contraceptive use. Women who use oral contraceptives should be strongly advised not to smoke. Use of oral contraceptives is associated with increased risk of several serious conditions, including thromboembolism, stroke, myocardial infarction, hepatic adenoma, gallbladder disease, hypertension. Practitioners prescribing oral contraceptives should be familiar with the following information relating to these risks.

1) *Thromboembolic Disorders and Other Vascular Problems.* An increased risk of thromboembolic and thrombotic disease associated with use of oral contraceptives is well established. Three principal studies in Great Britain and three in the United States have demonstrated an increased risk of fatal and nonfatal venous thromboembolism and stroke, both hemorrhagic and thrombotic. These studies estimate that users of oral contraceptives are 4 to 11 times more likely than nonusers to develop these diseases without evident cause. In a study of cerebrovascular disorders in women with and without predisposing causes, it was estimated that the risk of hemorrhagic stroke was 2.0 times greater than nonusers and the risk of thrombotic stroke was 4 to 9.5 times greater. An increased risk of myocardial infarction associated with the use of oral contraceptives has been reported. Studies conducted in the United Kingdom found that the greater the number of underlying risk factors for coronary artery disease (cigarette smoking, hypertension, hypercholesterolemia, obesity, diabetes, history of preeclamptic toxemia) the higher the risk of developing myocardial infarction, regardless of whether the patient was an oral contraceptive user or not. Oral contraceptives, however, were found to be a clear additional risk factor. In terms of relative risk, it has been estimated that oral contraceptive users who do not smoke (smoking considered a major predisposing condition to myocardial infarction) are about twice as likely to have a fatal myocardial infarction compared to nonusers who do not smoke. Oral contraceptive users who smoke have about a 5-fold increased risk of fatal infarction compared to users who do not smoke but about a 10- to 12-fold increased risk compared to nonusers who do not smoke. The amount of smoking is a very important factor. British investigators concluded that the risk of thromboembolism including coronary thrombosis is directly related to the dose of estrogen used in oral contraceptives; preparations containing 100 mcg or more of estrogen were associated with a higher risk of thromboembolism than those containing 50-80 mcg of estrogen. The relative risk of thromboembolic disease associated with progestin-only oral contraceptives has not been determined. Cases of thromboembolic disease have been reported in women using progestin-only products, and they should not be presumed to be risk-free. The overall excess mortality rate annually from circulatory diseases for oral contraceptive users was estimated to be 20 per 100,000 (ages 15-34, 5/100,000; ages 35-44, 33/100,000; ages 45-49 140/100,000), the risk being concentrated in older women, in those with a long duration of use, and in cigarette smokers. The highest risk was found in heavy cigarette smokers (15 or more cigarettes per day) who used oral contraceptives and were age 40 or older. Women who smoke should be advised not to use oral contraceptives. The use of oral contraceptives in women over age 40 with other risk factors is not recommended. The mortality associated with all of the methods of birth control is low compared to the risk of childbirth, with the exception of oral contraceptive users who smoke and are over age 40. The lowest mortality is associated with the condom or diaphragm backed up by early abortion. The risk of thromboembolic and thrombotic disease associated with oral contraceptives increases with age after approximately age 30 and for myocardial infarction is further increased by hypertension, hypercholesterolemia, obesity, diabetes, or history of preeclamptic toxemia, and especially by cigarette smoking. The physician and the patient should be alert to the earliest manifestations of thromboembolic and thrombotic disorders (e.g., thrombophlebitis, pulmonary embolism, cerebrovascular insufficiency, coronary occlusion, retinal thrombosis and mesenteric thrombosis). Should any of these occur or be suspected, the drug should be discontinued immediately.If feasible, oral contraceptives should be discontinued at least 4 weeks before surgery of a type associated with an increased risk of thromboembolism or prolonged immobilization. (2) *Ocular Lesions.* There have been reports of neuro-ocular lesions such as optic neuritis or retinal thrombosis associated with the use of oral contraceptives. Discontinue the medication if there is unexplained sudden or gradual, partial or complete loss of vision; sudden onset of proptosis or diplopia; papilledemia; or retinal vascular lesions, and institute appropriate diagnostic and therapeutic measures. 3) *Carcinoma.* Long term administration of either natural or synthetic estrogen in certain animal species increases the frequency of carcinoma of the breast, cervix, vagina and liver. In humans, one study investigated the first 21 cases of endometrial adenocarcinoma in women on oral contraceptives reported to a registry. Of those women without predisposing risk factors for this disease, nearly all occurred in women who had used a sequential oral contraceptive. No evidence has been reported suggesting an increased risk of endometrial cancer in users of conventional combination or progestin-only oral contraceptives. No increase in breast cancer in women taking oral contraceptives has been reported although one study reported an increased risk of breast cancer in subgroups of women treated using oral contraceptives with documented benign breast disease. There is at present no confirmed evidence from human studies of an increased risk of cancer associated with oral contraceptives. Close clinical surveillance of all women taking oral contraceptives is essential. In all cases of undiagnosed persistent or recurrent abnormal vaginal bleeding, appropriate diagnostic measures should be taken to rule out malignancy. Women with a strong family history of breast cancer or who have breast nodules, fibrocystic disease or abnormal mammograms should be monitored with particular care if they elect to use oral contraceptives. 4) *Hepatic Adenoma.* Benign hepatic adenomas have been found to be associated with the use of oral contraceptives. One study reported a higher risk associated with oral contraceptive formulations with high hormonal potency. Although benign and rare, hepatic adenomas may rupture and may cause death through intra-abdominal hemorrhage. This has been reported in short term as well as long term users of oral contraceptives. Two studies relate the risk with duration of contraceptive use, the risk being much greater after 4 or more years of oral contraceptive use. While hepatic adenoma is a rare lesion, it should be considered in women presenting abdominal pain and tenderness, abdominal mass, or shock. A few cases of hepatocellular carcinoma have been reported in women taking oral contraceptives. The relationship of these drugs to this type of malignancy is not known at this time. 5) *Use in Pregnancy. Birth Defects in Offspring and Malignancy in Female Offspring.* Fetal abnormalities have been reported to occur in the offspring of women who have taken progestogens and/or estrogens during pregnancy. It has been shown that females exposed in utero to diethylstibestrol, a nonsteroidal estrogen, have an increased risk of developing in later life a form of vaginal or cervical cancer that is ordinarily extremely rare. A high percentage of such exposed women (30% to 90%) have been found to have epithelial changes of the vagina and cervix. Although these changes are histologically benign it is not known whether this condition is a precursor of vaginal malignancy. Male children so exposed may develop abnormalities of the urogenital tract. Similar data are not available with the use of other estrogens but it cannot be presumed that they would not induce similar changes. The data suggest that the risk of limb reduction defects in exposed fetuses is somewhat less than 1 in 1000 live births. In the past, female sex hormones have been used during pregnancy in an attempt to treat threatened or habitual abortion. There is considerable evidence that estrogens are ineffective for these indications and there is no evidence from well-controlled studies that progestins are effective for these uses. Increases in chromosomal aberrations have been reported in women who become pregnant soon after ceasing oral contraceptive therapy. Embryos with these anomalies are virtually always spontaneously aborted. Whether there is an overall increase in spontaneous abortion of pregnancies conceived soon after stopping oral contraceptives is unknown. It is recommended that for any patient who has missed two consecutive periods, pregnancy should be ruled out before continuing the contraceptive regimen. If the patient has not adhered to the prescribed schedule, the possibility of pregnancy should be considered at the time of the first missed period and further use of oral contraceptives should be withheld until pregnancy has been ruled out. If pregnancy is confirmed the patient should be apprised of the potential risks to the fetus and the advisability of pregnancy continuation should be discussed in light of these risks. It is also recommended that women who discontinue oral contraceptives with the intent of becoming pregnant use an alternate form of contraception for a period of time before attempting to conceive. Many clinicians recommend three months. Administration of progestin-only or progestin-estrogen combinations to induce withdrawal bleeding should not be used as a test for pregnancy. 6) *Gallbladder Disease.* Studies have reported an increased risk of surgically confirmed gallbladder disease appearing after one year of oral contraceptive use and doubling of the risk after 4 or 5 years of use. 7) *Carbohydrate and Lipid Metabolic Effects.* A decrease in glucose tolerance has been observed in a significant percentage of patients on oral contraceptives. For this reason, prediabetic and diabetic patients should be carefully observed while receiving oral contraceptives. Increased serum levels of triglycerides and total phospholipids have been observed in oral contraceptive users. The clinical significance of this observation is unknown at this time. 8) *Elevated Blood Pressure.* An increase in blood pressure has been reported in women receiving oral contraceptives. The prevalence of hypertension in oral contraceptive users may be no higher than nonusers in the first year of oral contraceptive use but increases with longer exposure and in the fifth year of use is two and one-half to three times the reported prevalence in the first year. Women who previously had hypertension during pregnancy may be more likely to develop elevation of blood pressure when given oral contraceptives. 9) *Headaches.* The onset or exacerbation of migraine or development of headache of a new pattern which is recurrent, persistent or severe, requires discontinuation of oral contraceptives and investigation of the cause. 10) *Bleeding Irregularities.* Breakthrough bleeding, spotting and amenorrhea are frequent reasons for patients discontinuing oral contraceptives. In breakthrough bleeding, as in all cases of irregular bleeding from the vagina, nonfunctional causes should be borne in mind. In undiagnosed persistent or recurrent abnormal bleeding from the vagina, adequate diagnostic measures are indicated to rule out pregnancy or malignancy. If pathology has been excluded, time or change to another formulation may solve the problem. Changing to an oral contraceptive with a higher estrogen content, while potentially useful in minimizing menstrual irregularity, should be done only if necessary since this may increase the risk of thromboembolic disease. Women with a past history of oligomenorrhea or secondary amenorrhea or young women without regular cycles may have a tendency to remain anovulatory or to become amenorrheic after discontinuation of oral contraceptives. Women with these preexisting problems should be advised of this possibility and encouraged to use other contraceptive methods. (11) *Ectopic Pregnancy.* Ectopic as well as intrauterine pregnancy may occur in contraceptive failures. However, in oral contraceptive failures, the ratio of ectopic to intrauterine pregnancies is higher than in women not using oral contraceptives since the drugs are more effective in preventing intrauterine rather than ectopic pregnancy. The higher ectopic-intrauterine ratio has been reported with both combination products and progestin-only oral contraceptives. 12) *Breast-Feeding.* A small fraction of the hormonal agents in oral contraceptives has been identified in the milk of mothers receiving these drugs. The long-range effect to the nursing infant cannot be determined at this time.

Precautions: 1) A complete medical and family history should be taken prior to the initiation of oral contraceptives. Examination should include special reference to blood pressure, breasts, abdomen and pelvic organs, including Papanicolaou smear and relevant laboratory tests. As a general rule, oral contraceptives should not be prescribed for longer than 1 year without another physical examination being performed. 2) Under the influence of estrogen-progestogen preparations, preexisting uterine leiomyomata may increase in size. 3) Patients with a history of psychic depression should be carefully observed and the drug discontinued if depression recurs to a serious degree. 4) Because oral contraceptives may cause some degree of fluid retention, conditions which might be aggravated by fluid retention, such as convulsive disorders, migraine syndrome, cardiac or renal insufficiency or asthma require careful observation. 5) Patients with a past history of jaundice during pregnancy have an increased risk of recurrence of jaundice while receiving oral contraceptive therapy. If jaundice develops in any patient receiving such drugs, the medication should be discontinued. 6) Steroid hormones may be poorly metabolized in patients with impaired liver function and should be administered with caution in such patients. 7) Oral contraceptive users may have disturbances in normal tryptophan metabolism which may result in a relative pyridoxine deficiency. The clinical significance of this is yet to be determined. 8) Serum folate levels may be depressed by oral contraceptive therapy. This may complicate subsequent pregnancy with regard to folate deficiency. 9) The pathologist should be advised of oral contraceptive therapy when relevant specimens are submitted. 10) Certain endocrine and liver function tests and blood components may be affected by estrogen-containing oral contraceptives: a. Increased sulfobromophthalein retention. b. Increased prothrombin and factors VII, VIII, IX, and X; decreased antithrombin 3; increased norephinephrine-induced platelet aggregability. c. Increased thyroid binding globulin (TBG) leading to increased circulating total thyroid hormone, as measured by protein -bound iodine (PBI), T_4 by column, or T_4 by radioimmunoassay. Free T_3 resin uptake is decreased, reflecting the elevated TBG, free T_4 concentration is unaltered. d. Decreased pregnanediol excretion. e. Reduced response to metyrapone test. 11) The active yellow tablets and the inert green tablets in the 28 day regimen of Ovcon-35 contain FD&C Yellow No. 5 (tartrazine) which may cause allergic-type reactions (including bronchial asthma) in certain susceptible individuals. Although the overall incidence of FD&C Yellow No. 5 (tartrazine) sensitivity in the general population is low, it is frequently seen in patients who also have aspirin hypersensitivity.

Information for the Patient: Detailed Patient Labeling has been prepared for use by the patient and has been made available for distribution by the pharmacist.

Drug Interactions: Reduced efficacy and increased incidence of breakthrough bleeding have been associated with concomitant use of rifampin. A similar association has been suggested with barbiturates, phenylbutazone, phenytoin sodium, ampicillin and tetracycline.

Adverse Reactions: An increased risk of the following serious adverse reactions has been associated with the use of oral contraceptives (see **Warnings**): Thrombophlebitis, pulmonary embolism, coronary thrombosis, cerebral thrombosis, cerebral hemorrhage, hypertension, gallbladder disease, congenital anomalies. There is evidence of an association between the following conditions and the use of oral contraceptives, although additional confirmatory studies are needed: Mesenteric thrombosis; benign hepatomas; neuro-ocular lesions, e.g., retinal thrombosis and optic neuritis. The following adverse reactions have been reported in patients receiving oral contraceptives and are believed to be drug related: Nausea and/or vomiting, usually the most common adverse reactions, occur in approximately 10% or less of patients during the first cycle (other reactions, as a general rule, are seen much less frequently or only occasionally); gastrointestinal symptoms (such as abdominal cramps and bloating); breakthrough bleeding; spotting; change in menstrual flow; dysmenorrhea; amenorrhea during and after treatment; temporary infertility after discontinuance of treatment; edema; chloasma or melasma which may persist; breast changes (tenderness, enlargement, and secretion); change in weight (increase or decrease); change in cervical erosion and cervical secretion; possible diminution in lactation when given immediately postpartum; cholestatic jaundice; migraine; increase in size of uterine leiomyomata; rash (allergic); mental depression; reduced tolerance to carbohydrates; vaginal candidiasis; changes in corneal curvature (steepening), intolerance to contact lenses. The following adverse reactions have been reported in users of oral contraceptives, and the association has been neither confirmed nor refuted: Premenstrual-like syndrome, cataracts, changes in libido, chorea, changes in appetite, cystitis-like syndrome, headache, hemolytic uremic syndrome, nervousness, dizziness, hirsutism, loss of scalp hair, erythema multiforme, erhythema nodosum, hemorrhagic eruption, vaginitis, porphyria.

Acute Overdosage: Serious ill effects have not been reported following acute ingestion of large doses of oral contraceptives by young children. Overdosage may cause nausea, and withdrawal bleeding may occur in females.

Distribution of CA 125 in embryonic tissues and adult derivatives of the fetal periderm

Hildur Hardardottir, MD,[a] Tim H. Parmley II, MD,[a] J. Gerald Quirk, Jr., MD, PhD,[a] M. Melinda Sanders, MD,[b] Frank C. Miller, MD,[a] and Timothy J. O'Brien, PhD[a]

Little Rock, Arkansas

New murine monoclonal antibodies to a partially purified CA 125 antigen were developed and identified as M 2 and M 11. With immunohistochemical techniques, these new antibodies and OC 125 antibody were used to search for CA 125 in embryonic tissues and adult apocrine sweat glands and mammary glands. The embryonic skin, the periderm, expressed CA 125 antigen and its adult derivatives, the mammary glands and apocrine sweat glands, expressed CA 125 while in the active state of secretion. In a 6-week-old formalin-fixed and paraffin-embedded ectopic embryo specimen, antibodies M 2 and M 11 recognized CA 125 in the periderm, the notochord, the myocardium, the pericardium, the gastroenteric tract, enteric duct remnants in the umbilical cord (vitelline and allantoic ducts), the mesonephric duct, and the amnion. OC 125 staining of these formalin-fixed specimens was either very faint or absent. In a formalin-fixed and paraffin-embedded specimen of apocrine sweat glands from the axilla, antibodies M 2 and M 11 detected CA 125 antigen intracellularly in the secretory cells. Again no staining was observed with OC 125 antibody. In a frozen and acetone-fixed specimen of lactating mammary glands, antibodies M 2 and OC 125 detected CA 125 antigen intraductally. Colostrum and milk collected from 25 mothers at various stages post partum had mean CA 125 levels of 34,213 U/ml in colostrum, 1469 U/ml at 3 to 7 days, and 105 U/ml at 5 to 26 weeks. (Am J Obstet Gynecol 1990;163:1925-31.)

Key words: CA 125, periderm, apocrine glands, breast milk

In 1981 Bast and colleagues[1] identified OC 125, a monoclonal antibody that recognizes the CA 125 epitope associated with a high molecular weight glycoprotein antigen complex. Since then, the antigen has been localized immunohistochemically in many ovarian carcinomas of epithelial origin with the use of OC 125 antibody.[2-4] It has also been found in the serum of women with these tumors and has been widely used as a tumor marker in selected cases.[5-7] The antigen also has been measured in the serum of patients with endometrial,[8] pancreatic,[5] and pulmonary carcinoma[9] as well as in patients with pelvic inflammatory disease,[10] endometriosis[11-13] and in pregnancy.[14] In pregnancy it is found not only in maternal serum but also in amniotic fluid.[15, 16] With the use of immunohistochemical techniques, CA 125 has been detected intracellularly in the periderm and amnion of a 7-week human embryo.[17] After differentiation of the embryonic coelomic epithelium CA 125 is found in the pleura, pericardium, peritoneum, and in the müllerian duct derivatives: the corpus uteri, the cervix uteri, and the fallopian tube.[17, 18] In the adult, some antigen expression is maintained in these tissues.[18, 19]

Recently we developed new murine monoclonal antibodies to a preparation that contained partially purified CA 125 (unpublished data). With OC 125 and these new antibodies, M 2 and M 11, we studied immunohistochemically the tissues of a formalin-fixed, paraffin-embedded ectopic embryo of approximately 6 weeks' gestational age. Adult derivatives of the fetal periderm and their secretory products were also evaluated by both immunohistochemistry and direct immunoradiometric assay.

Material and methods

Antibody preparation. Monoclonal antibodies to antigen containing CA 125 were produced by immunizing Balb/c mice with partially purified CA 125 antigen followed by lymphocyte fusion with a mouse myeloma cell line (unpublished data). Hybrids were screened for CA 125–specific antibodies and positive cultures were cloned by dilution for hybridoma selection. Productive clones were grown in the peritoneal cavity of pristane-treated mice and monoclonal antibodies harvested from ascites. This ascites fluid was aliquotted and stored at −70° C for further use.

Tissue samples. A formalin-fixed and paraffin-embedded ectopic embryo specimen, apocrine sweat glands from the axilla, groin, and a dermoid cyst, as well as fetal membranes from a normal placenta at term

were provided by the Pathology Department at the University of Arkansas for Medical Sciences.

Sections were cut at 4 μm intervals and mounted on gelatin-coated slides. After deparaffinization in toluene (three changes, 5 minutes each) and rehydration through serial ethanol baths, tissue sections were permeabilized with a detergent (0.05% Triton-X 100, 10 minutes) and acid (0.2 mol/L hydrochloric acid, 20 minutes) before endogenous peroxidase activity was blocked with hydrogen peroxide (0.03% in 100% methanol, 30 minutes). Secondary antibody–human antigen interactions were blocked with γ-globulin (immunoglobulin G) fraction of serum from nonimmune rabbits (DAKO, Santa Barbara, Calif.) 30 minutes at room temperature. The sections were then incubated overnight at room temperature with one of the following murine antihuman antibodies: M 2 diluted 1 : 50, 1 : 100, and 1 : 500, M 11 diluted 1 : 100 and 1 : 500, and OC 125 diluted 1 : 50, 1 : 100, and 1 : 500 in phosphate buffer solution. As a negative control, mouse ascites was similarly incubated on adjacent sections at the same dilution as was the primary antibody. A subsequent 30-minute incubation with secondary antibody, rabbit antimouse, was followed by a 30-minute incubation with mouse peroxidase-antiperoxidase, both at room temperature. The chromogen used to stain immunoreactive cells was 3-amino-9-ethylcarbazole. Between steps, the sections were washed in Tris hydrochloride saline solution buffer for three washings of 5 minutes each. The secondary antibody, the mouse peroxidase-antiperoxidase, and the chromogen were all supplied by DAKO. Tissue sections were counterstained with Gill's hemotoxylin, bathed in lithium carbonate solution, and coverslipped with warm glycerol-gelatin.

Frozen lactating mammary gland tissue was supplied by the Cooperative Human Tissue Network, Birmingham, Ala. A specimen was obtained 14 hours post mortem, 3 weeks after a third-trimester abortion. Fetal membranes from a normal pregnancy at term were obtained fresh and snap-frozen in isopentane and liquid nitrogen. Sections of 4 μm were cut at −20° C, fixed in acetone for 15 minutes, and then stored at −70° C until processed.

After thawing for 1 hour at room temperature, sections were processed in a similar manner as described for paraffin-embedded tissues, starting with permeabilization.

Colostrum and breast milk. Breast milk was collected from a total of 25 healthy postpartum women according to a protocol approved by the Human Research Advisory Committee. Group I (n = 8) consisted of first milk samples only; colostrum, collected at the time of delivery or up to 3 days post partum. Group II (n = 7) consisted of samples collected 3 to 7 days post partum. Group III (n = 10) samples were collected 5 to 25 weeks post partum. The milk was centrifuged at 2000 rpm for 20 minutes and fat was removed prior to storage (−70° C). CA 125 levels were determined with standard test kits (supplied by Centocor, Malvern, Pa.). Protein concentrations were determined according to the method of Bradford[20] with reagents (from Biorad Inc., Richmond, Calif.).

Results

In the embryo (approximately 6 weeks' gestation) CA 125 antigen was detected by antibodies M 2 and M 11 in the periderm and the amnion (Fig. 1). In formalin-fixed sections CA 125 antigen was not detected by the OC 125 antibody. Nanbu et al.[17] previously described CA 125 in these tissues in a 7-week-old embryo with the use of OC 125 antibody and frozen sections. Inasmuch as formalin-fixation per se may be destructive or cause masking of some epitopes, we compared staining in frozen and formalin-fixed sections of term amnionic membranes. In frozen sections, OC 125, M 2, and M 11 all stained the amnion. However, formalin fixation and paraffin embedding of this tissue resulted in a marked decrease in the intensity of staining by OC 125, whereas staining intensity produced by antibodies M 2 and M 11 was much less affected (Fig. 1).

In sections of formalin-fixed embryonic tissue, CA 125 antigen is distinctly localized intracellularly in the notochord, enteric duct remnants (vitelline and allantoic ducts), umbilical cord, myocardium, and pericardium by M 2 and M 11 antibodies (Fig. 2). Extracellular localization of the antigen was detected surrounding the mesonephric duct (wolffian duct), the upper gastrointestinal tract, and possibly on the surface of the trophoblast by M 2 and M 11 antibodies (Fig. 2). OC 125 poorly stained or did not stain these tissues.

In the adult, CA 125 antigen was detected in peridermal derivatives: the apocrine sweat glands and the mammary glands. In formalin-fixed sections of apocrine sweat glands from the axilla, CA 125 antigen is detected intracellularly by antibodies M 2 and M 11, but not by OC 125 (Fig. 3). In frozen sections of lactating mammary glands (provided by the Cooperative Human Tissue Network), antigen was detected by OC 125 and M 2 antibodies intraductally (Fig. 4). Considering the intraductal location of antigen in lactating mammary glands, as opposed to its intracellular localization in the apocrine sweat glands, CA 125 might be anticipated to be present in breast milk. On assay, very high levels of antigen were found in colostrum (Group I, n = 8), ranging from 15,000 to 60,000 U/ml with a mean of 34,213 ± 5904 U/ml. CA 125 antigen levels

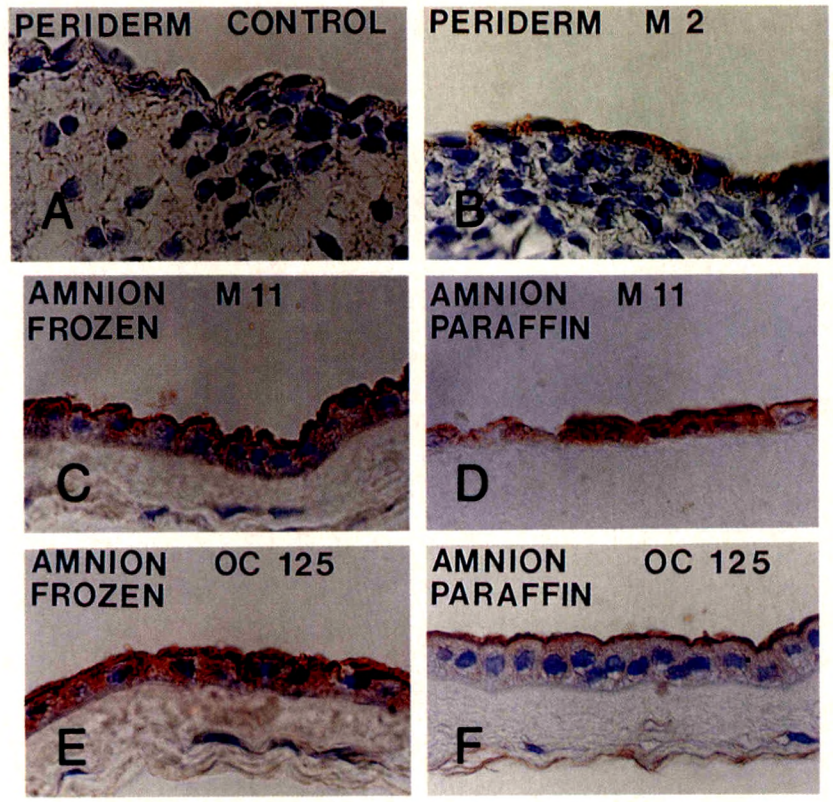

Fig. 1. Fetal membranes from normal pregnancy at term. **A**, Periderm; mouse ascites control. **B**, Periderm; M 2 antibody. CA 125 antigen is localized primarily intracellularly throughout epithelial surface of embryo; periderm, as recognized by antibody M 2. **C**, Fetal membranes frozen and acetone-fixed; M 11 antibody. Staining is more intensely associated with cell surface. (Original magnification ×1000.) **D**, Fetal membranes formalin-fixed and paraffin-embedded; M 11 antibody. Maximal intensity of staining is seen on cell surfaces along with some less prominent intracellular staining. (Original magnification ×1000.) **E**, Fetal membranes frozen and acetone-fixed specimen; OC 125 antibody. Intense staining of cell surfaces along with some intracellular staining is observed. (Original magnification ×1000.) **F**, Fetal membranes formalin-fixed and paraffin-embedded; OC 125 antibody. There is slight, but clear, staining of cell surfaces. (Original magnification ×1000.)

in groups II and III were much lower, ranging from 1130 to 1755 U/ml (mean, 1469 ± 92 U/ml) and 28 to 203 U/ml (mean, 105 ± 16 U/ml), respectively (Fig. 5). Statistically significant differences in CA 125 antigen levels between groups I and II and between groups II and III ($p < 0.001$) were determined with the Student t test (Fig. 5). Mean protein levels in groups I, II, and III were 45, 12, and 9 mg/ml, respectively. CA 125 specific activity (units CA 125 per milligram protein) ranged from 478 to 1395 in group I, 82 to 160 in group II, and 3 to 27 in group III (Fig. 5).

Comment

With the use of the newly developed antibodies M 2 and M 11, we confirm Nanbu's observation of CA 125 antigen in embryonic periderm and amnion. Colocalization of these new monoclonal antibodies with OC 125 in various tissues, support the notion that the new antibodies recognize epitopes that are closely associated with those recognized by OC 125. Whereas the antigen recognized by OC 125 has not been completely described, it is generally considered to be a high molecular weight glycoprotein (>200,000 daltons).[20] The configuration of the immunoradiometric assay used to measure CA 125 (Centocor, Malvern, Pa.) with single monoclonal antibody (OC 125) in a sandwich assay, implies that the CA 125 molecule contains more than one epitope for antibody binding. Independent data using immunoprecipitation and western blotting indicate that the epitopes recognized by OC 125, M 2, and M 11 reside on a common molecular species of approximately 250,000 daltons (unpublished data).

Because antibodies M 2 and M 11, but not always OC 125, detected antigen in the embryonic periderm and

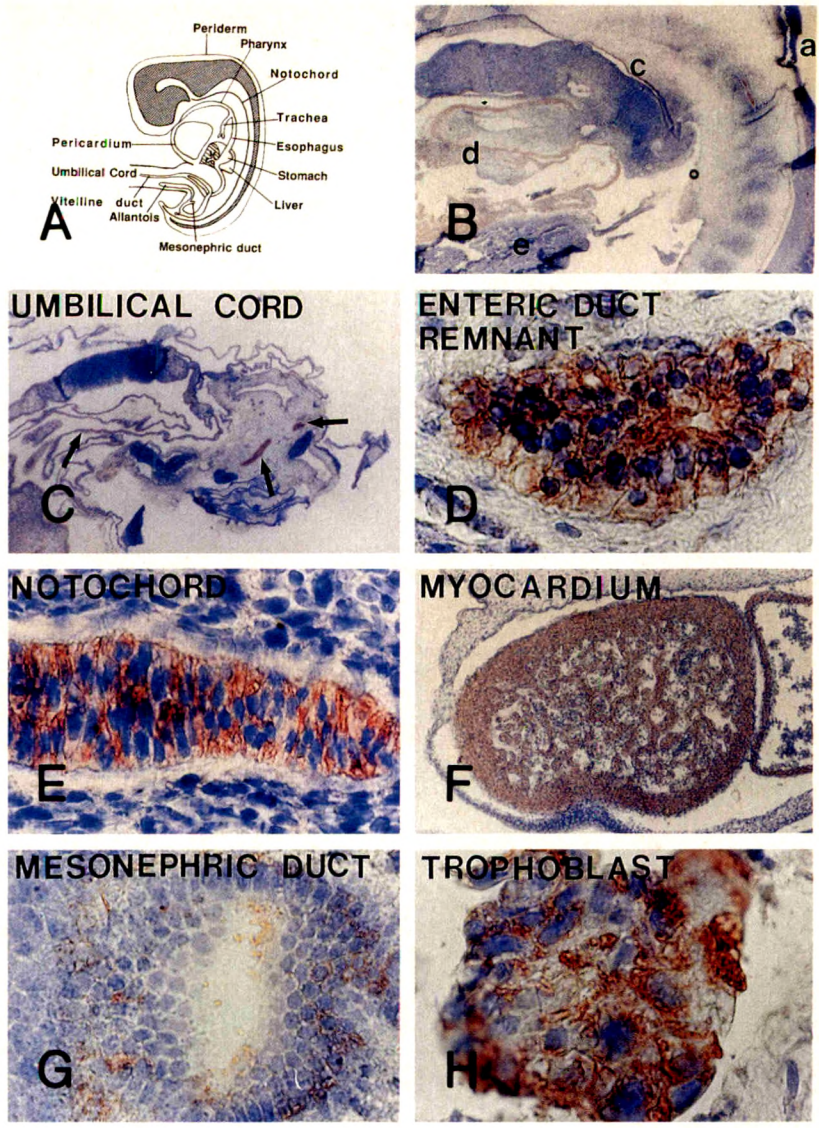

Fig. 2. Embryo, gestational age approximately 6 weeks, formalin-fixed and paraffin embedded. **A,** Human embryo, approximately 6 weeks old in hemisection, illustrating periderm, notochord, endodermal canal, pericardium, and liver. **B**, Human embryo, approximately 6 weeks old. **a**, Neural tube; **b**, notochord; **c**, pharynx; **d**, myocardium; **e**, liver. **C**, Umbilical cord; with enteric duct remnants (vitelline duct and allantoic duct) both showing immunoreactivity intracellularly when exposed to M 2 and M 11 antibodies. Also illustrated is amnion with prominent staining. (Original magnification ×100.) **D**, Enteric duct remnant in umbilical cord at increased magnification, illustrating clearly intracellular distribution of antigen. (Original magnification ×1000.) **E**, Notochord, cut tangentially, reacts with both M 2 and M 11 antibodies. Staining produced is evenly distributed intracellularly. (Original magnification ×1000.) **F**, Myocardium, ventriculus to left and atrium to right. Staining is produced by M 2 and M 11 antibodies inside myocardial cells and in pericardium *(bottom right)*. (Original magnification ×400.) **G**, Mesonephric duct. Epitopes recognized by M2 and M 11 antibodies are localized on cell surfaces, encircling this structure, along with some less prominent localization intraluminally. (Original magnification ×1000.) **H**, Fragment of trophoblastic tissue shows reactivity to both M2 and M 11 antibodies. Apparently staining is localized intracellularly and extracellularly. (Original magnification ×1000.)

amnion in formalin-fixed and paraffin-embedded sections, we speculate that epitopes recognized by OC 125 were either masked or damaged by the formalin-fixative or damaged by the hot paraffin (60° C) in routinely processed specimens. Accordingly, we divided the term amnion in two parts and processed one as a frozen specimen and the other routinely in formalin and paraffin. Although OC 125 antibody does detect the antigen in formalin-fixed term amnion in which the antigen is abundantly present, it is strikingly less prominent than when the tissue is frozen. The intensity of staining obtained by M 2 and M 11 was much less af-

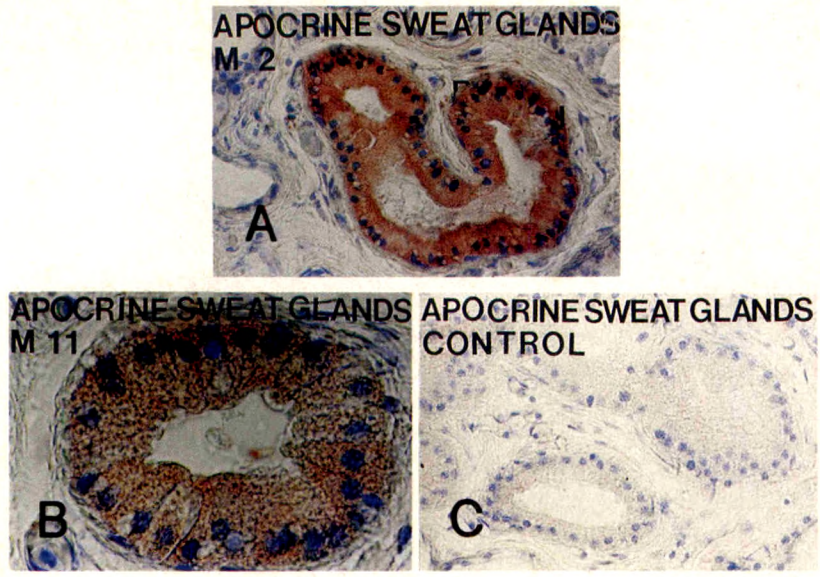

Fig. 3. Normal adult apocrine sweat glands from axilla, formalin-fixed and paraffin-embedded tissue sections. **A**, CA 125 antigen is detected intracellularly in secretory epithelium of apocrine sweat glands by M 2 antibody. (Original magnification ×400.) **B**, Apocrine sweat glands at higher magnification show same pattern produced by M 11 antibody. Fig. 4. Normal lactating mammary glands, frozen and acetone-fixed tissue sections. (Original magnification ×1000.) **A**, Lactating mammary glands; M 2 antibody. In lactating breast CA 125 antigen is detected in secretory product intraductally by M 2 antibody, but not intracellularly in epithelial cells. **B**, Lactating mammary glands; OC 125. OC 125 antibody produces similar staining pattern as M 2 antibody. **C**, Lactating mammary glands; mouse ascites control.

fected by formalin fixation and paraffin embedding. We conclude that the epitopes recognized by M 2 and M 11 are less subject to loss when the tissue is formalin fixed and paraffin embedded, compared with the epitopes recognized by OC 125. When CA 125 antigen is found in abundance in tissues the method of processing is not critical; however, when antigen is present in relatively low abundance, as may be the case in early embryonic development, processing of the specimen may be of significant importance.

Our results show a widespread distribution of CA 125 antigen in tissues that arise from all three embryonic germ layers. CA 125 was detected from the ectoderm in the periderm, mammary glands, and apocrine sweat glands; CA 125 was detected from the mesoderm in the myocardium and the mesonephric duct; and CA

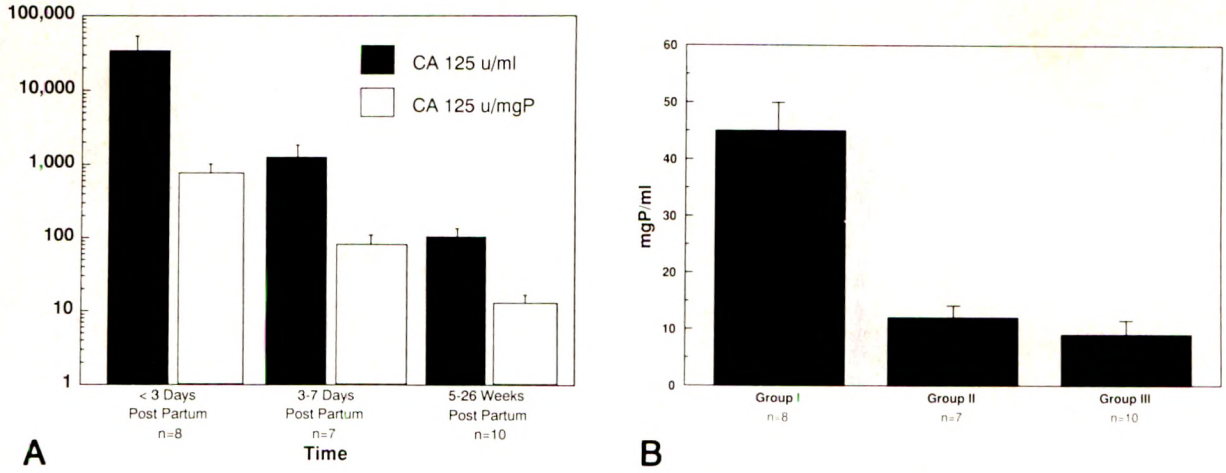

Fig. 5. CA 125 and protein levels in colostrum and breast milk. **A**, CA 125 levels and specific activity (units per milligram protein) in colostrum and breast milk at 0 to 3 days, 3 to 7 days and 5 to 26 weeks after parturition. **B**, Protein levels in colostrum and breast milk.

125 was detected from the endoderm in the enteric ducts (vitelline and allantoic ducts) and the gastrointestinal tract. Such a wide distribution of the antigen in developing tissues indicates an important role for CA 125 during early embryonic development and may ultimately help us to understand why it is produced by various malignancies later in life.

The observation of CA 125 on embryonic surfaces (i.e., the periderm, the amnion, the enteric duct remnants, the gastrointestinal tract, and the mesonephric duct) led us to speculate a potential role for this molecule in the prevention of cell-to-cell adhesion (i.e., prevention of collapse or closure of these structures). In the adult, the antigen is found on the surface of cells that line the pericardium, pleura, and peritoneum suggesting that CA 125 antigen may serve the same role in these organs during adult life.

Hanisch et al.[21] described CA 125 in a single sample of breast milk collected 4 days post partum. In this study, CA 125 was measured in colostrum and milk at various stages of lactation. High concentrations of CA 125 were found in colostrum and early milk, declining rapidly during the first week of lactation and reaching a steady level in mature milk. Colostrum is known to have some antiinfective properties and protect the offspring from various infections, especially gastrointestinal infections. This property is attributed mainly to the presence of secretory immunoglobulin A, which is the main protein in colostrum,[22] but also to other substances such as lysozyme, lactoferrin, and lactoperoxidase. Secretory immunoglobulin A is found in high concentrations in early milk, as described by McClelland et al.[23] and then falls rapidly to a low but constant level in a fashion similar to CA 125. Whether this association has a clinical significance or whether CA 125 contributes to the antiinfective properties of colostrum is unknown.

The presence of CA 125 antigen in apocrine glands raises the question of its role in the secretory process per se. Glands with an apocrine mode of secretion, which are known to express CA 125 antigen, include endometrial glands,[16] bronchoalveolar glands,[19] mammary glands, and apocrine sweat glands. Other glands (i.e., eccrine sweat glands), which are the same embryonic origin as apocrine sweat glands (ectodermal), do not express CA 125 antigen. This could imply a different function of these sweat glands or be related to different secretory processes.

The expression of CA 125 antigen in the early developing embryo and in the secretory products of apocrine glands suggests a broad developmental or biologic function that remains to be elucidated. Cloning of the CA 125 gene and structural analysis of the gene product may provide further insight into the biology of this antigen.

We wish to acknowledge the generous contributions of OC 125 antibody and CA 125 IRMA kits by Vincent Zurowski, Jr., of Centocor, and the contribution of tissue specimens from the Cooperative Human Tissue Network, Southwestern Division, Katherine Sexton, Tissue Procurement, University of Alabama at Birmingham.

Comparison of norethindrone and medroxyprogesterone acetate with natural progesterone and estradiol in stimulating prolactin production from cultured endometrial stromal cells

Jay H. Levin, MD, Sharon A. Tonetta, PhD, and Rogerio A. Lobo, MD
Los Angeles, California

Progestins stimulate prolactin production from endometrial stromal cells in culture. We compared the potencies of the synthetic progestins norethindrone and medroxyprogesterone acetate to natural progesterone in inducing stromal prolactin production. Modifications of the culture system provided an increase in stromal cell yield, thus permitting multiple comparisons from the treatment of cells from a common endometrial sample. The effects of high-dose estradiol also were evaluated in this system. The findings suggest relative potencies of 50:1 for medroxyprogesterone acetate and progesterone. Norethindrone gave intermediate and more variable responses. Estradiol potentiated prolactin production from only submaximal progestins doses. The differences between the progestin effects, in large measure, were due to differential culture growth as reflected by culture mass. Compared to controls and estradiol alone, all the progestins induced much greater prolactin production. Thus during decidualization, progestins probably promote both stromal growth and intracellular prolactin production. High-dose estradiol may not interfere with these events. (Am J Obstet Gynecol 1990;163:1932-8.)

Key words: Endometrium, stromal cells, prolactin, progestins

Human endometrium is known to undergo dramatic morphologic and functional changes after ovulation.[1, 2] In vitro models have shown that prolactin (PRL) is produced by decidualized endometrium,[3] increases with progestin stimulation,[4-6] and originates primarily from the stroma.[6-9] While it has been suggested that the synthetic progestins norethindrone and medroxyprogesterone acetate may be more potent than natural progesterone in stimulating stromal cells,[10] the relative potencies of these progestins for stimulating PRL production have not been demonstrated.

Estradiol has been shown to diminish the progestin-dependent stimulation of PRL production from follicular phase endometrial explants[5] as well as from stromal cell cultures when a high dose of estrogen was used.[11] In more recent studies using stromal cells, high-dose estrogen, such as achieved during controlled ovarian hyperstimulation, has been shown to enhance both medroxyprogesterone acetate[6] and progesterone[8] stimulatory effects on PRL production.

This study was designed to compare the potencies of norethindrone, medroxyprogesterone acetate, and progesterone for inducing endometrial decidualization as reflected by in vitro stromal PRL production, and to determine whether this secretion is due to increased cellular production or culture growth. Further, we wished to evaluate the effects a high dose of estradiol in this model. To this end, we modified existing culture systems[11-13] to increase cell yield to enable such parallel comparisons.

Material and methods

Four sets of cultures were performed from each tissue specimen obtained during the midluteal phase of two premenopausal, eumenorrheic women, ages 43 and 44. The endometrium was obtained immediately after hysterectomy for symptomatic uterine descensus. The midluteal phase status was documented by menstrual timing and confirmed histologically by the method of Noyes et al.[14]

Stromal cells were isolated from glands by a method adapted from that described by previous investigators.[11-13] The endometrial tissue was transported to the culture laboratory in refrigerated, sterile Dulbecco's modified Eagle's media (DMEM) (Gibco Laboratories, Grand Island, N.Y.) and minced within 30 minutes of removal from the uterus. Enzymatic digestion was then performed in a solution containing 0.1% collagenase, type II (Sigma Chemical Co., St. Louis), 0.1% hyaluronidase, type III (Sigma), 0.1% protease, type XIV (Sigma), and 0.1% ethylenedinaminetetraacetic acid

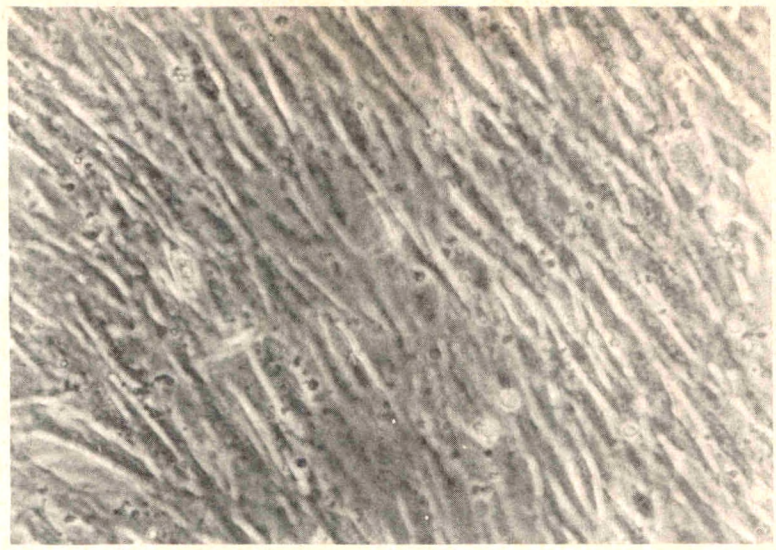

Fig. 1. Phase-contrast photomicrograph of stromal cells in culture.

(Sigma) for 30 minutes at 37° C with gentle stirring. After washing to quench the digestion process, the tissue was filtered sequentially through 75 μm and 38 μm sieves to obtain a highly enriched stromal cell suspension. This procedure yields 40 to 90 × 10^6 viable endometrial cells per specimen, with 80% to 90% total viability as determined by 0.4% trypan blue exclusion (Sigma).

Primary cultures were established with 10^6 viable cells per milliliter per culture well in DMEM with 10% fetal calf serum (Irvine Scientific, Santa Ana, Calif.), 5 μg/ml transferrin (Sigma), 10 μg/ml insulin (Sigma), penicillin, streptomycin, and fungizone (Gibco) at 37° C in a 95% air/5% carbon dioxide atmosphere. This concentration of cells resulted in efficient plating of purified stromal cell populations reaching confluence by 48 to 72 hours of culture. Purity of the cell population was confirmed by well-established morphologic criteria[15-17] (Fig. 1).

Media were changed every 48 hours for a total of 14 days. Steroid treatments were begun with initial plating and selected from the following: progesterone at doses of 50 and 500 ng/ml (P50 and P500); medroxyprogesterone acetate at doses of 10 and 100 ng/ml (M10 and M100); norethindrone at doses of 1, 10, and 100 ng/ml (N1, N10, and N100); estradiol at 5 ng/ml (E); and each of the progestin doses in combination with estradiol 5 ng/ml (P50E, P500E, M10E, M100E, N1E, N10E, and N100E). Controls consisted of media alone (C). In each experiment, controls and all treatment perturbations were performed in quadruplicate cultures. At the conclusion of the experiment, the cells were removed from the culture plates with a 0.1% solution of trypsin-ethylenediaminetetraacetic acid.

Collected media were assayed for PRL by a modification of the technique of Sinha et al.[18] The assay was performed with a 24-hour preincubation period and dilution of the anti-PRL antibody (AFP-2284C2 obtained from the National Institutes of Health, Bethesda, Md.) to the concentration of 1:200,000. Maximum binding ranged from 21% to 25%. This allowed an assay sensitivity of 400 pg/ml. Intraassay coefficients of variation were 15.4%, 7.3%, and 10.3% for the low, mid, and high ranges, respectively. The interassay coefficients of variation were 9.7%, 9.2%, and 9.9% for the low, mid, and high ranges, respectively. Mean PRL concentrations of pools at the low, mid, and high ranges were 1.2, 7.8, and 29 μg/ml, respectively. Samples containing levels of PRL greater than the assay's upper limit were diluted. Assay blanks generated counts consistent with <0.2 ng/ml.

Protein content was determined for each of the cultures. After trypsinization, the cultured cells were washed twice and stored at −70° C as pellets covered with buffered solution. The samples were then thawed and sonicated just before protein determination using the bicinchonincic acid protein assay[19] (Pierce Chemical Company, Rockford, Ill.).

Statistical testing included application of analysis of variance to test for differences between treatments and linear regression analysis was used to determine significant relationships.

Results

Prolactin production data (mean ± SD) for each of the quadruplicate culture experiments are depicted in Tables I and II and are henceforth referred to as experiments 1 and 2. Values for the initial 48 hours were all <400 pg/ml and are not depicted. Fig. 2 depicts the dynamics of this system. Stimulation with the highest

M100E	3.6 ± 0.5	12.2 ± 3	21 ± 6	88 ± 4	172 ± 4	199 ± 14

Values expressed as mean ± SD.
*$p < 0.05$, all progestin treatments > control.
†$p < 0.05$, M100 and M10 > P50; and P50E > P50.
‡$p < 0.05$, M100 > M10 > P50; M10E > M10; and P50E > P50.

dose of medroxyprogesterone acetate (M100) resulted in exponentially increased PRL production, starting from day 4 to 6. Controls and estradiol alone resulted in only transient increases that peaked on day 6 and declined thereafter. The levels achieved in the controls and with estradiol alone were significantly lower than with any of the progestins.

Experiment 1. Experiment 1 compared P50, M10, M100, P50E, M10E, and M100E with controls (Table I). Prolactin production from control cultures peaked on day 6 at 3.9 ± 0.7 ng/ml and thereafter declined to <0.4 ng/ml by day 10. The progestins P50, M10, and M100 exerted continued stimulation to much higher levels (32 ± 9, 119 ± 6, and 173 ± 14 ng/ml) by day 14 (Fig. 3). Addition of estradiol to each of these progestins resulted in day 14 levels of 166 ± 18, 187 ± 25, and 199 ± 14 ng/ml for P50E, M10E, and M100E, respectively (Fig. 3). Thus M100 stimulation was greater than M10 by 45% ($p < 0.05$), and both M100 and M10 were more potent than P50 by 440% ($p < 0.05$) and 272% ($p < 0.05$), respectively. In addition, although estradiol potentiated both P50 (by 419%; $p < 0.05$) and M10 (by 57%; $p < 0.05$), M100 remained unaffected (p = NS). These dose relationships and the potentiation by estradiol both became apparent by day 6 and were statistically significant at day 10 (Table I).

Protein content of these cultures was 360 ± 25, 328 ± 44, 367 ± 32, 513 ± 20, 456 ± 16, 522 ± 79, and 558 ± 54 μg per culture for control, P50, M10, M100, P50E, M10E, and M100E, respectively (Table III). Dividing PRL production by protein content accounted for some but not all the differences in PRL production. For M100 this ratio was greater than for both controls ($p < 0.05$) and P50 ($p < 0.05$) but not for M10 (p = NS) (Table III). Therefore when compared with controls and P50, M100 stimulated both greater culture mass and greater PRL production per mass.

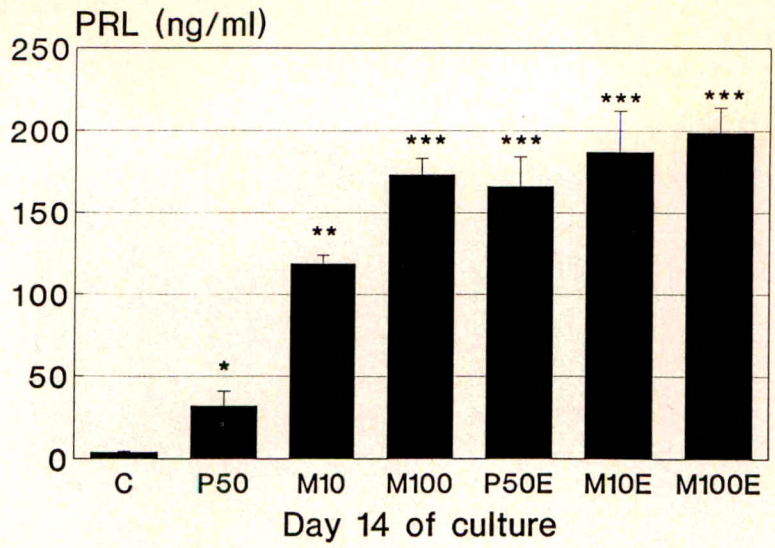

Fig. 3. Comparison of day-14 PRL production from cultures in experiment 1. (By analysis of variance: *asterisk*, $p < 0.05$ vs controls *[C]; double asterisks*, $p < 0.05$ vs P50 and *C; triple asterisks*, $p < 0.05$ vs M10, P50, and *C;* all steroid stimulations significantly greater than *C.*)

N100E	3.3 ± 0.6	20 ± 9	33 ± 14	48 ± 5	54 ± 10	61 ± 8

Values are expressed as mean ± SD.
*$p < 0.05$, E > control.
†$p < 0.05$, N1 < N10; N1E > N1.
‡$p < 0.05$, N1 < N10; P50 < P500; and N1E > N1.

When compared with M10, however, M100 stimulated only greater increases in culture mass with equivalent relative PRL production.

For control cultures this ratio was very much lower than for any of the progestin treatments, suggesting a failure to induce comparable PRL production, even when compared to P50, which resulted in similar final culture mass. However, there was a good correlation between protein content and day-14 PRL production ($r = 0.79$; $p < 0.001$).

Experiment 2. Experiment 2 compared P50, P500, M10, M100, N1, N10, and N100 alone and with estradiol to control and estrogen (Table II). Production from controls peaked by day 6 at 2.9 ± 1.1 ng/ml and thereafter declined <0.4 ng/ml by day 10. The progestins P50, P500, M10, M100, N1, N10, and N100 stimulated much greater production of 58 ± 3, 72 ± 10, 83 ± 13, 91 ± 14, 54 ± 9, 76 ± 9, and 81 ± 6 ng/ml by day 14, respectively (Fig. 4). Addition of estradiol to each of these progestins resulted in day-14 levels of 64 ± 12, 45 ± 7, 70 ± 13, 88 ± 17, 77 ± 15, 79 ± 10, and 61 ± 8 ng/ml, respectively. Estradiol alone provided only transient stimulation that peaked at 8.4 ± 0.7 ng/ml by day 6. This was greater than for controls

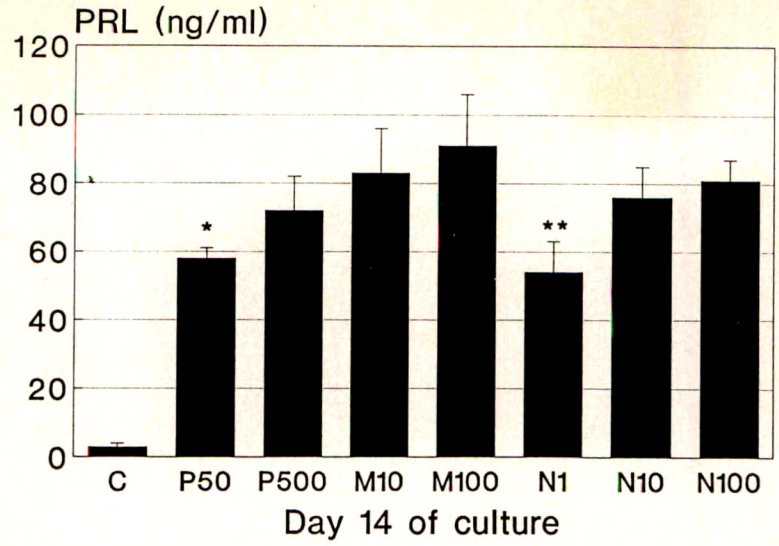

Fig. 4. Comparison of day-14 PRL production from cultures in experiment 2. (By analysis of variance: *asterisk*, $p < 0.05$ vs P500, M10, M100, N10, and N100; *double asterisks*, $p < 0.05$ vs N10, N100, M10, M100, and P500; all progestin stimulations greater than *C*.)

Values are expressed as mean ± SD.
*$p < 0.05$, control, E, and N1 < all other treatments; N1E > N1.
†$p < 0.05$, control and E < < other treatments.

($p < 0.05$) but much less than for any of the progestins.

As depicted in Fig. 4, N1 was less potent than both N10 (by 29%, $p < 0.05$) and N100 (by 33%; $p < 0.05$), but N10 was equipotent to N100. P50, which was equal to N1, exerted less stimulation than M10 (29%; $p < 0.05$) and M100 (36%; $p < 0.05$) as well as N10 and N100. Although not rigorously significant by analysis of variance, isolated *t* tests revealed that P500 was more potent than P50 (72 ± 10 vs 58 ± 3; $p < 0.05$). Additionally, P500 stimulation equaled that of M10, N10, and N100.

When added to the progestins, estradiol significantly potentiated only N1 (77 ± 15 vs 54 ± 9; $p < 0.05$). Estradiol had no such dramatic effect on the other progestin doses. Although M10E and N100E had slightly lower production than M10 and N100, these differences were not significant (p = NS). P500E exerted less stimulation than P500 ($p < 0.05$), but appeared to be an aberrant, isolated observation. The other progestins of equal or greater potency were not affected negatively. Prolactin production for P500E already had fallen by day 4, which was before any differential stimulation should have been manifest in this model (Table II).

The protein content of these cultures are listed in Table IV. For the progestin treatments, differences in PRL production were paralleled by the differences in culture mass. The addition of estradiol potentiated

growth only for the least potent progestin doses, P50 ($p < 0.05$), N1 ($p < 0.05$), and N10 ($p < 0.05$). The protein content correlated well with day-14 PRL production ($r < 0.58$; $p < 0.001$), and further normalizing PRL production to culture mass diminished the apparent differences in progestin responses. However, differential culture mass again could not explain the very large differences in PRL production between the progestins and controls or estrogen.

Comment

Endometrial stromal PRL production, which serves as a marker of decidualization, responds to progestin stimulation in a dose-dependent manner.[8] Tseng et al.[10] reported relative potencies of 135:90:70 for medroxyprogesterone acetate:norethindrone:progesterone in the stimulation of aromatase activity from luteal stromal cells cultured for 3 days. Other comparisons of progestin potencies rely upon results obtained from cultures of different tissue specimens. We wished to assess the progestin potencies for stimulating production of PRL in a system designed to compare differential responses of cells obtained from a common tissue.

This study confirmed the dose-response nature of the progestin stimulation of stromal cells and has established relative potencies for norethindrone and medroxyprogesterone acetate compared with progesterone in stimulating stromal PRL production. Our findings suggest that norethindrone and medroxyprogesterone acetate are equipotent at a dose of 10 ng/ml, but that medroxyprogesterone acetate (and not norethindrone) exerts a greater stimulation at a higher dose (100 ng/ml). Both of the synthetic progestins at 10 ng/ml resulted in stimulation statistically indistinguishable from natural progresterone at 500 ng/ml. Thus the relative potency ratio for medroxyprogesterone acetate:progesterone is suggested to be 50:1, with more variable potency responses occurring with norethindrone (5- to 50-fold greater) compared to progesterone.

Although estrogens may increase endometrial progesterone receptors in vitro[20] and in vivo,[21] the role of luteal estrogens in the regulation of stromal prolactin production remains less clear. Previous work has suggested that depending on the dose used in culture, estrogens alone may stimulate,[8, 11] have no effect,[6, 11] or inhibit slightly[11] this stromal function. When combined with progestins, estradiol has been shown to exert negative,[5] neutral,[6] or positive[8, 9] effects.

This study has shown that estradiol at 5 ng/ml may stimulate low levels of stromal PRL production, but that this effect is transient. Furthermore, while estradiol may potentiate the progestins, this effect was limited to the lower progestin doses. While both P50 and N1 stimulation may be enhanced by estradiol, M100 was not. Results from the progestin doses of intermediate potency (P500, M10, N10, and N100) were more variable. In one case M10 was potentiated by estradiol, whereas in other cultures none of the intermediate progestins were enhanced. This suggests that high levels of luteal estrogens may influence endometrial decidualization but that this may occur only during submaximal progestin stimulation.

In this model plating equal numbers of cells to each culture served to normalize the system. Therefore the relative protein content reflected differences in culture "growth," which may have been from cell proliferation, cell enlargement, or deposition of extracellular matrix. That the "growth" trends paralleled PRL production differences suggests that for the different progestin stimulations much of the differential secretory activity was linked to the differences in culture mass. However, in control and estrogen only cultures, the ratios of peak PRL production/protein content were far less than for any of the progestin treatments. Thus, the dramatic stimulation by progestins compared to control and estrogen most probably resulted from induction of cellular PRL production capability and not from the relatively smaller differences in "growth."

In conclusion, we have established relative potencies for progestin stimulation of endometrial stromal PRL production. This appears to be dependent on both culture "growth" and induction of PRL synthesis. Estradiol alone has little effect, but may actually enhance both of these aspects of culture dynamics under conditions of submaximal progestin stimulation.

A rabbit model for bacteria-induced preterm pregnancy loss

Raymond A. Dombroski, MD,[a] Donna S. Woodard, PhD,[b] Michael J. K. Harper, PhD,[a] and Ronald S. Gibbs, MD[a]

San Antonio, Texas

Bacterial infection has been implicated in premature labor in humans. To elucidate mechanisms and potential intervention strategies, we sought to develop a model of infection-induced pregnancy loss in rabbits. On day 21 (70% of gestation), each uterine horn was inoculated hysteroscopically with 0.2 ml containing saline solution or 10^6 cfu *Escherichia coli* or *Bacteroides bivius* or *Fusobacterium necrophorum*. Fetal viability was assessed. Animals were sacrificed at various times or as delivery occurred. Serum progesterone and amniotic fluid prostaglandins were measured. Cultures and histologic sections were prepared. Compared with the saline solution group, *E. coli* and *F. necrophorum*–inoculated rabits were significantly more likely to deliver (16 of 16 and six of seven with mean times of 31.9 ± 10.7 and 28.3 ± 11.5 hours, respectively for *E. coli* and *F. necrophorum*). Positive amniotic fluid cultures for the *E. coli* group were found in 11 of 12 (92%) and for the *F. necrophorum* group in three of three cases (100%). Histologic inflammation was seen heavily in both the *E. coli* and *F. necrophorum* groups, whereas it was absent in the saline solution group. Inoculation with *B. bivius* led to a much lower pregnancy loss rate (eight of 32) and less histologic inflammation despite positive uterine cultures in most animals. This model may provide an opportunity to determine mechanisms of clinical or subclinical intraamniotic infection and to test intervention strategies. (Am J Obstet Gynecol 1990;163:1938-43.)

Key words: Premature labor, infection, rabbit, hysteroscopy, histology

Considerable data suggest that bacterial infection may be a cause of preterm birth. Histologic chorioamnionitis and positive membrane cultures are more common after preterm birth,[1] and various bacteria and their products have been found in the amniotic fluid of women with preterm labor.[2, 3] Bacterial lipopolysaccharides, moreover, are capable of stimulating the production of prostaglandins, platelet-activating factors, and cytokines in intrauterine and other tissues.[4, 5]

Systemic administration, including intravenous and intraperitoneal routes, of bacterial endotoxin to pregnant animals has been shown to precipitate pregnancy loss in several species.[6-9] In a rabbit model we tested the hypothesis that intrauterine bacterial infection causes preterm pregnancy loss. The methods reported represent a novel approach to the study of infection-induced preterm birth.

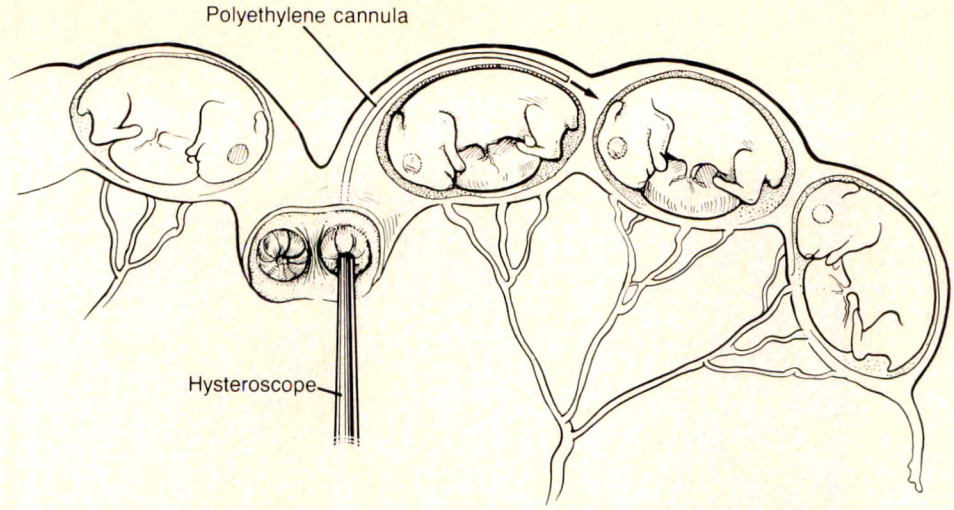

Fig. 1. Schematic representation of experimental inoculation of uterine horns.

Material and methods

Virgin Cambridge-New Zealand White Cross rabbits (weight >3 kg) were obtained from a local vendor (Penn Acres Ranch, Wimberly, Tex.). The animals were housed in the animal facility with a 12-hour-day/12-hour-night cycle and provided water as desired and feed (170 gm of rabbit pellets per day). After acclimatization for a minimum of 2 weeks, artificial insemination, followed immediately by an intravenous injection of 50 IU human chorionic gonadotropin, was performed. At this facility, these methods result in a pregnancy rate of 95%.

On day 21 of gestation (normal gestational length, 33 to 34 days), does were anesthetized with an intramuscular injection of a mixture of ketamine-promethazine-xylazine (0.5 ml/kg). After vaginal preparation with a povidone-iodine solution, a Storz 27020B hysteroscope (provided by Storz Instrument, St. Louis) was introduced into the vagina and the cervices were visualized. Through the operating port, a 0.06-inch outside diameter polyethylene cannula was introduced transcervically into each horn of the uterine cavity a minimum of 6 cm (Fig. 1). The same injection of either a bacterial inoculum (see below) or pyrogen-free saline solution (0.2 ml) was then made into each horn.

Bacterial inocula were prepared for the following: *Escherichia coli* ATCC 12014, *Bacteroides bivius* ATCC 29303, and *Fusobacterium necrophorum* ATCC 25286. For preparation of the *E. coli* inoculum, a tube of thioglycollate medium was inoculated aerobically and grown for 6 to 8 hours before concentration and washing. *B. bivius* and *F. necrophorum* were grown in chopped meat broth for 12 to 16 hours. These latter cultures were maintained and washed under strict anaerobic conditions. For each organism, media were removed by centrifugation and the bacterial pellet was washed (by resuspension and recentrifugation) three times in phosphate-buffered saline solution before final suspension in an appropriate volume of buffer to yield 10^7 to 10^8 cfu/ml. Because the volume of the inoculum was 0.2 ml, each horn was injected with approximately 10^6 to 10^7 cfu. Final suspensions were plated semiquantitatively before inoculation in each case to confirm colony count. Finally, a remaining aliquot was plated to check for viability after the 1- to 2-hour interval required for inoculation.

In a pilot experiment with *E. coli* to evaluate inoculum size, no difference was observed between inocula of 10^3 to 10^4 and 10^7 to 10^8 cfu per horn.

After inoculation animals were observed for signs of sepsis and delivery. Animals were killed by an intravenous injection of 5 ml pentobarbital sodium when delivery was recognized or after 7 days. Rectal temperatures were taken at the time of operation, 24 hours later, and when put to death.

When animals were put to death, blood, peritoneal fluid, chorioallantoic-amniotic fluid (when available), and decidua were cultured aerobically and anaerobically on 5% sheep blood agar, chopped meat broth, and thioglycollate broth. Gram stains of amniotic fluid, peritoneal fluid, and decidua were prepared. The viability of fetuses remaining in utero was noted. A blood sample was obtained for progesterone determination, which was performed in a routine radioimmunoassay.[10] Amniotic fluid was obtained for measurements of prostaglandins F_2 and E_2. The prostaglandins were measured by the radioimmunoassay procedure described by Harper et al.[11] and modified by Jones et al.[12] without prior extraction. The antibodies were obtained from Advanced Magnetics Inc. (Cambridge, Mass.). The in-

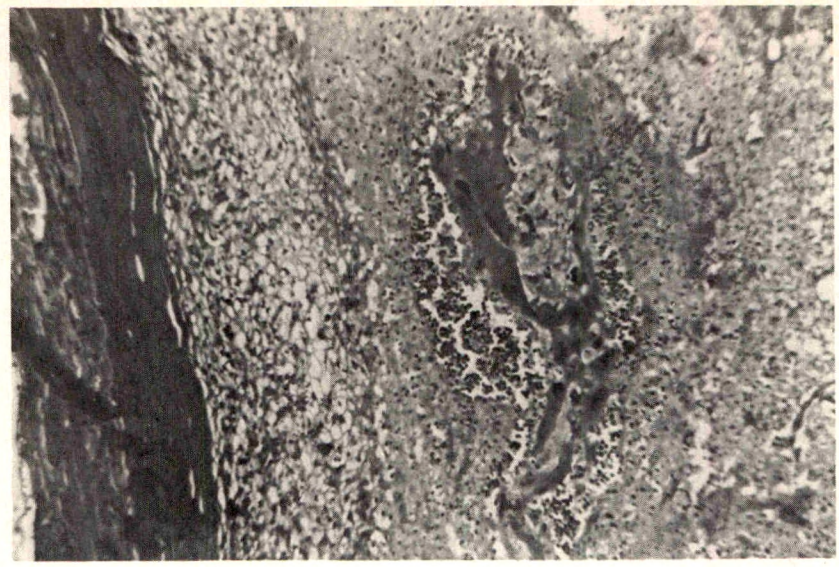

Fig. 2. Representative histologic section of placental zone of separation from *E. coli*—inoculated animal when put to death shows heavy infiltrate of polymorphonuclear leukocytes. (Hematoxylin and eosin. Original magnification ×40.)

Table I. Pregnancy outcomes by intrauterine inoculum

Inoculum	*n*	*Delivered (No.)*	*Died (No.)*	*Time to delivery (hr, mean ± SD)*	*No. with live fetuses*	*Purulent exudate in utero (No.)*
Saline solution	9	2	0	134 ± 19.8	7	2
E. coli	16	16*	0	31.9 ± 10.7†	0	7
F. necrophorum	7	6‡	3	28.3 ± 11.5†	0	1
B. bivius	32	8	0	90.5 ± 39.5	28	10

*$p < 0.0001$, compared with number delivered in saline solution group.

†$p < 0.05$ for *E. coli* and *F. necrophorum* groups compared with saline solution group for mean time to delivery, by Newman-Keuls method.

‡$p < 0.05$, compared with number delivered in saline solution group.

terassay and intraassay coefficients of variations were, 7% and 8.7%, respectively, for prostaglandin F and 11.5% and 8.8% for prostaglandin E. Indomethacin (10 μg/ml) was added to sample tubes before collection. Prostaglandins were not extracted before assay because pilot work demonstrated no difference between values with and without extraction. A portion of the uterine horn containing a placenta was fixed in 10% neutral buffered formalin for histologic examination.

Histologic descriptions used standard terms.[13, 14] Categoric data were analyzed by uncorrected χ^2 or Fisher's exact test. Interval and ratio measurements were compared by one-way analysis of variance and Newman-Keuls multiple comparisons or Student's *t* statistic when appropriate. All tests were two-tailed and for independent samples. When assumptions were not met, equivalent nonparametric statistics (Kruskall-Wallis analysis of variance, Mann-Whitney U) were used. Statistical analyses were performed on an IBM PC with the True Epistat program.

Results

When put to death, five animals (7.2%) were found to have had inadvertent perforation of the uterus and were excluded from further analysis (saline solution group, one animal; *B. bivius*, three, *E. coli*, none, *F. necrophorum*, one). Pregnancy outcomes are shown in Table I. Additional pertinent observations were noted. In the two animals delivered in the saline solution group, both also had several dead fetuses remaining in utero. Both also contained bloody amniotic fluid and grossly purulent uterine contents. In the remaining seven rabbits, all undelivered fetuses were alive; there was no purulence.

In the *F. necrophorum* group, abruptio placentae was noted in three animals with dead fetuses remaining in utero. Uterine horns and placentas appeared pale in all seven rabbits in this group.

In the *B. bivius* group, eight animals had delivery of one or more pups (Table I). Of these, six had one or more live pups remaining in utero when put to death, but two of the six also contained dead fetuses.

Table II. Development of fever* by intrauterine inoculum

Group	*No. of animals with fever*		*p (vs saline solution)*	
	At 24 hr	*When put to death*	*At 24 hr*	*When put to death*
Saline solution	0 (n = 9)	0 (n = 9)		
E. coli	6 (n = 12)	6 (n = 10)	0.02	0.01
F. necrophorum	2 (n = 6)	2 (n = 4)	0.14	0.08
B. bivius	1 (n = 32)	5 (n = 32)	0.78	0.27

Fever was defined as rectal temperature ≥104.00° F; see text. Numbers in parentheses represent total number of animals at this time.

Table III. Culture results by intrauterine inoculum

Group	*Culture site*								
	Amniotic fluid			*Peritoneal fluid*			*Decidua*		
		Positive			*Positive*			*Positive*	
	n	*No.*	*%*	*n*	*No.*	*%*	*n*	*No.*	*%*
Saline solution	9	1	11	9	1	11	9	2	22
E. coli	12	11	92	12	9	75	Not done		
F. necrophorum	3	3	100	4	0	0	4	4	100
B. bivius	30	10	33	32	0	0	29	23	79

No. positive is the number of animals that were culture positive for the organisms inoculated. In the saline solution group one grew enterococci at all three sites and one grew enterococci in decidua only. Both of these animals delivered offspring.

When overall mean temperatures at 24 hours and when put to death were compared with those at time of operation, we found a small but significant increase at these times only in the saline solution group (102.01° ± 0.39° F at operation vs 102.42° ± 0.31° at 24 hours vs 102.61° ± 0.43° F when put to death, $p < 0.05$), but not in the other groups. Although there was no significant temperature change overall in the *B. bivius* group, the mean temperatures were higher when put to death in the eight animals that delivered than in the 24 that did not (104.16° ± 1.77° vs 102.70° ± 0.71°, respectively; $p = 0.02$).

Because of wide variance in the three bacterial groups, we analyzed temperature changes alternatively. If fever in rabbits was defined as 104.00° F (i.e., mean of all temperatures at operation + 2 SD), analysis by inoculum is shown in Table II.

Culture results are shown in Table III. Rabbits inoculated with *E. coli* and *F. necrophorum*, if positive, cultured only the organism inoculated. In the *B. bivius* group, several animals had positive cultures for other organisms. Three cultured enterococci as the only organism at any site in decidua. These do not appear in Table III. None of these animals delivered any offspring. Three other animals had additional organisms isolated together with *B. bivius* at the same site or a different one. One of these grew enterococci from chorioallantoic-amniotic fluid, peritoneal fluid, and decidua alone with *B. bivius* in the decidua. This animal delivered offspring. A second animal had both *B. bivius* and enterococci in the decidua. In the third, γ-streptococci were isolated from amniotic fluid and decidua in combination with *B. bivius*. Neither of these two animals delivered offspring.

Table IV. Serum progesterone level when animals were put to death, classified by intrauterine inoculum

Group	*n*	*Serum progesterone (ng/ml, mean ± SD)*
Saline solution	7	11.20 ± 9.19*
E. coli	7	5.79 ± 5.42*
F. necrophorum	4	5.99 ± 1.20*
B. bivius	25	7.91 ± 3.62*
Delivered	6	5.81 ± 0.89†
Undelivered	19	8.57 ± 3.91†

*Differences between these four groups are not significant by Kruskall-Wallis analysis.

†The difference between these two subgroups is ($p = 0.03$) by Mann-Whitney U test but may reflect a difference in gestational age.

Progesterone levels were obtained from several animals when put to death (Table IV). Kruskall-Wallis analysis showed no differences between groups (saline solution, *E. coli*, *F. necrophorum*, or *B. bivius*), although variances within groups were considerable. In a separate analysis by Mann-Whitney U test, the difference between the subgroups of *B. bivius* animals (i.e., deliv-

Table V. Chorioallantoic-amniotic fluid prostaglandin E_2 and $F_{2\alpha}$ levels

Group	*n*	*Prostaglandin E_2**	*Prostaglandin $F_{2\alpha}$**
Saline solution	6	786.5 ± 878	351.3 ± 322
E. coli	9	1951.4 ± 796	2802.8 ± 2120
B. bivius	13	915.5 ± 549	755.2 ± 770
Delivered	4	1103.2 ± 543	1201.7 ± 1316
Undelivered	9	832.0 ± 562	556.7 ± 312

*Values for *E. coli* group are significantly higher as compared with the saline solution and *B. bivius* groups ($p < 0.05$) by Newman-Keuls multiple comparisons. Differences between delivered and undelivered subgroups of *B. bivius*–inoculated rabbits are not significantly different by Mann-Whitney U test.

ered vs undelivered) reached statistical significance ($p = 0.03$) but may reflect a difference in gestational age.

Chorioallantoic-amniotic fluid prostaglandin levels when put to death are shown in Table V. The levels of both prostaglandins were significantly elevated in *E. coli*–treated animals compared with all other groups. The differences observed between delivered and undelivered *B. bivius* animals were not significant. Again, variances are great and sample sizes are small.

The histologic findings varied considerably by inoculating organism. Saline solution–treated animals that remained undelivered showed no inflammatory exudate in any layers. Occasionally, margination of white blood cells was noted in subplacental vessels. *E. coli*–treated animals displayed heavy infiltration of the endometrium, amanion, and chorion with polymorphonuclear leukocytes (Fig. 2). Scatterd foci of polymorphonuclear leukocytes were found in the zone of separation, decidua, and subplacenta. Scattered inflammatory cells were found within maternal sinuses of the placenta but the overall vascular anatomy of the placenta was maintained.

Animals inoculated with *F. necrophorum* displayed inflammation and necrosis of the endometrial glandular elements. Infiltration by white blood cells of the membranes was prominent, but the zone of separation and the subplacenta were generally spared. The most striking findings consisted of extensive abruptio placenta and engorgement of maternal vascular channels with the placenta.

B. bivius–treated animals showed inflammatory cells in all layers, although the degree of inflammation was less than with other inocula. The placenta was generally spared.

Comment

In these experiments we developed an animal model for bacterial-induced pregnancy loss. We chose hysteroscopic introduction, rather than transabdominal inoculation, to mimic ascending infection more closely. We chose *E. coli* because of its clinical importance in maternal and neonatal infection and because it produces large amounts of endotoxin (lipopolysaccharide). Subsequently, we chose *B. bivius* and *F. necrophorum* because of their frequent isolation either in clinically evident intraamniotic infection in preterm pregnancies[15] or from amniotic fluid in patients in preterm labor.[2]

We have demonstrated that hysteroscopic introduction of *E. coli* and *F. necrophorum* into the rabbit uterine cavity at approximately 70% of gestation regularly led to pregnancy loss, with a mean of 30 hours. In saline solution–inoculated animals, bacteria, presumably from the lower genital tract, were occasionally introduced into the uterine cavity, which was accompanied by pregnancy loss. However, in the absence of such inadvertent introduction, atraumatic, hysteroscopic introduction of saline solution did not result in pregnancy loss.

With *E. coli* and *F. necrophorum* inoculation, pregnancy loss was accompanied by fever in the does, microbiologic and histologic confirmation of infection-inflammation when animals were put to death, fetal death, and occasionally, maternal death. Because there was considerable variance in progesterone levels when animals were put to death, we observed no significant differences in mean levels by inoculation group.

However, because serum progesterone levels may truly be lower in infected animals, it is tempting to speculate. Perhaps a rise in serum prostaglandin $F_{2\alpha}$ (or at least in uterine vein levels) could adversely affect luteal function and thus decrease progesterone levels. In the rabbit, luteolysis probably occurs systematically via prostaglandin $F_{2\alpha}$ in the venous drainage from the uterus and not, for example, via lymphatic drainage to the renal or iliac lymph nodes.[16, 17]

Mean amniotic fluid prostaglandin levels were elevated in all groups inoculated with bacteria compared with the saline solution group, but because of small numbers and wide variance, these increases achieved significance only for the *E. coli* group.

A different response was observed in animals inoculated with *B. bivius*, compared with the *E. coli* and *F. necrophorum* groups. Although the organism was detectable in the decidua in most animals (79%), it was less commonly isolated from the chorioallantoic-amniotic fluid (33%) and was accompanied by less his-

tologic inflammation. Compared with *E. coli* and another gram-negative anaerobe *(F. necrophorum)*, *B. bivius* led to a milder clinical response. Overall, the clinical response in the *B. bivius* group was not dissimilar from the saline solution group. However, if the *B. bivius* group is compared with the noncontaminated saline solution controls, then *B. bivius* inoculation presents a clinical picture reminiscent of subclinical infection—positive cultures, low-grade inflammation, mild maternal symptoms, occasional pregnancy loss, and absence of fetal death in utero.

Depending on the organisms selected, this model may provide an opportunity to explore the mechanism of clinical intraamniotic infection or infection-induced premature birth. The model may be further used to test intervention strategies.

We thank Barry Korinick and Patricia St. Clair for their technical assistance.

In vitro inhibition of esterase activity in amniotic fluid: Comparison with bacterial cultures

Iffath Abbasi Hoskins, MD, Joseph Katz, PhD, Faith J. Frieden, MD, Steven A. Ordorica, MD, and Bruce K. Young, MD

New York, New York

Assessment of leukocyte esterase activity in amniotic fluid for the rapid and reliable diagnosis of chorioamnionitis has been demonstrated previously. We compared in vitro inhibition of esterase activity in amniotic fluid with bacterial cultures to identify the origins of the specific esterases released by the infecting organisms. One hundred forty-one samples were tested (90 uninfected, 51 infected). Each sample was evaluated for Gram stain, cultures, and an in vitro esterase assay followed by ebelactone inhibition. Forty-two patients had positive amniotic fluid cultures. Ebelactone produced varying degrees of inhibition of esterase activity (range, 20% to 60%) in the uninfected samples and in those infected with gram-negative organisms. There was no inhibition in the samples infected with gram-positive organisms. Thus different groups of bacteria may elicit the production of different and specific esterases in infected amniotic fluid, as shown by the differences in in vitro inhibition. (Am J Obstet Gynecol 1990;163: 1944-7.)

Key words: Chorioamnionitis, leukocyte esterase, inhibition, bacterial cultures

Chorioamnionitis is a common diagnostic dilemma for the obstetrician. Rapid and accurate diagnosis poses the most significant problem. The clinical diagnosis is usually based on a constellation of symptoms that include maternal fever, tachycardia, uterine tenderness, foul odor of amniotic fluid, leukocytosis, and fetal tachycardia. However, there is uncertainty with regard to accurate and early diagnosis and laboratory confirmation.[1]

Because leukocytes are known to be released in response to infections, examination of the amniotic fluid for their presence may be useful in the evaluation for chorioamnionitis. The neutrophilic leukocytes released contain several esterases that are not present in serum, urine, or body tissues.[2, 3]

We have previously described the reliability of an in vitro spectrophotometric assay of leukocyte esterase activity in amniotic fluid for the prediction of chorioamnionitis. In this study we compared in vitro inhibition of this activity with the results of bacterial cultures in an attempt to identify the origins of the specific esterases that are released by the infecting organisms.

Material and methods

Sterile specimens of amniotic fluid were obtained from 141 antepartum patients who had undergone transabdominal amniocenteses during the second and third trimesters for genetic studies, rhesus isoimmunization, and fetal lung maturity studies, or to rule out chorioamnionitis. All patients included in the study had intact membranes. Ninety samples were obtained from uninfected patients and 51 from women with chorioamnionitis as determined by the presence of at least two of the following criteria: maternal pyrexia (temperature >37.8° C), leukocytosis (white blood cell count >12,000/mm^3), uterine tenderness, and fetal tachycardia (heart rate >160 beats/min). Each sample was divided into three parts: one each for Gram stain, aerobic and anaerobic cultures, and the in vitro esterase activity. The in vitro assay was performed by adding known amounts of amniotic fluid (10 λ) to solutions containing 20λ of a 5 μmol/L solution of *p*-nitrophenyl hexanoate in dimethyl sulfoxide and 1 ml of buffer (0.1 mol/L phosphate, pH 7.4). The change in optical density at wavelength 405 nm ($\Delta OD_{405}/10^{-3}$) was calculated from the initial slopes of the change in absorbance at 405 nm as a function of time. One unit of activity was defined as a change of 1 absorbance unit/min. Then, 10 λ of a nonspecific esterase inhibitor ebelactone (1 mg/ml) was added to each aliquot, and the $OD_{405}/10^{-3}$ was again calculated to measure the degree of inhibition of esterase activity in the sample. The results were compared with those obtained from amniotic fluid aerobic and anaerobic cultures.

Gram staining was performed with commercial reagents (crystal violet, safranin, and Gram's iodine; Difco Laboratories, Detroit) under standard conditions. The presence of white blood cells and microorganisms was noted, and a semiquantitative assessment was made

after examination of 20 high-power fields. A positive Gram stain was defined as one containing any microorganisms per high-power field.

The amniotic fluid aliquots for cultures were collected in plastic, capped syringes and transported to the laboratory immediately after collection for inoculation into the culture media. Positive cultures were defined as those containing one or more types of organisms in excess of 10^4 cfu/ml. For purposes of this study, if more than one organism was isolated on culture, the predominant organism was labeled the causative one. A positive leukocyte esterase enzyme assay was defined as a value >12 enzyme activity units.[4]

The sensitivity, specificity, and predictive values for the diagnostic parameters were calculated. A χ^2 analysis was performed to compare the results of the esterase assay and the inhibition assay between the uninfected and infected groups. Statistical significance was defined as a p value <0.05.

Results

The relationship between the Gram stain, cultures, leukocyte esterase activity, and inhibition in the uninfected and infected samples is shown in Table I. There were 90 uninfected amniotic fluid samples; 58 were obtained during the second trimester. One sample showed gram-positive cocci on Gram stain, there were no positive amniotic fluid cultures, and the leukocyte esterase activity of all samples was within the normal ranges as previously defined (>12 enzyme activity units). Three of the 32 uninfected samples obtained in the third trimester had positive Gram stains (two cases with gram-positive cocci and one with gram-negative rods). One of these samples also showed a positive amniotic fluid culture with organisms >10^4 cfu/ml (group B streptococcus).

Table III. Pathogens identified on amniotic fluid cultures

Organism	*Uninfected (n = 90)*	*Infected (n = 51)*
Aerobic gram-positive		
Group B streptococci	1	6
Enterococci	0	10
Anaerobic gram-positive		
Streptococci	0	0
Aerobic gram-negative		
E. coli	0	21
Enterobacteriaceae	0	0
Anaerobic gram-negative		
B. fragilis	0	3
F. nucleatum	0	1

Nineteen of the 51 infected samples were obtained from second-trimester amniotcenteses. Of these, only seven had positive Gram stains (gram-positive cocci, three cases; gram-negative rods, three; gram-negative cocci, one). All seven samples also had positive amniotic fluid cultures (group B streptococcus, two; *Escherichia coli*, four; *Bacteroides fragilis*, one). An additional six samples had positive amniotic fluid cultures but neg-

Table IV. Comparison of bacterial cultures and inhibition of leukocyte esterase activity

	n	*Leukocyte esterase activity* (range)*	*Ebelactone* (range)*
Uninfected	90	2.8-7.0	0.6-1.4
Infected	51	17.0-19.6	
Positive cultures	41

*Absorbance units.

ative Gram stains (group B streptococcus, two; *E. coli*, two; *B. fragilis*, two). Thirty-two samples were obtained from third-trimester amniotcenteses. Of these, 18 had positive results on both Gram stains and amniotic fluid cultures, and 10 had negative Gram stains but positive amniotic fluid cultures.

Forty-five of the 51 infected samples had positive leukocyte esterase activity (>12 enzyme activity units). Two of the six fluids with negative leukocyte esterase activity were second-trimester samples. One of these also had a positive amniotic fluid culture for group B streptococcus. The remaining four were from third-trimester samples. All four had negative amniotic fluid cultures.

The reliability of the diagnostic indices is shown in Table II. Gram stains of the amniotic fluid samples were not found to be highly sensitive (36.8%, second trimester; 56.3% third trimester). This finding is similar to a previous study in which we found Gram stains to be only 62% sensitive in third-trimester amniotic fluid samples.[5] The specificity of the Gram stains in second- and third-trimester fluids was 98.3% and 90.6%, respectively. In this study the sensitivity of amniotic fluid cultures was only 68.4% in the second-trimester samples and 87.5% in the third-trimester samples.

The various organisms identified on cultures are shown in Table III. When more than one organism was grown from an amniotic fluid sample, the infection was referred to as being caused by "mixed aerobic or anaerobic flora," and those samples were eliminated from analysis for this study. The paucity of anaerobic isolates obtained in this study may reflect bacterial fastidiousness or death or the limitations of the laboratory facilities that provided the results. There was one positive culture in the 90 uninfected samples. This was a third-trimester amniotic fluid sample in which group B Streptococcus ($>10^4$ cfu/ml) was isolated. There were 41 positive amniotic fluid cultures in the infected samples. As seen in the table, *E. coli* and enterococci were the two most common organisms identified in this group. However, if a positive culture was defined as one containing organisms $>10^2$ cfu/ml, then all 51 samples were positive. The organisms identified as $>10^2$ cfu/ml were as follows: group B streptococcus, one case; enterococcus, one case; streptococcus, one case; *E. coli*, two cases; Enterobacteriaceae, one case; *B. fragilis*, four cases.

The in vitro inhibition of the leukocyte esterase activity in the uninfected and infected samples with the nonspecific esterase inhibitor ebelactone is shown in Table I. The inhibition of the leukocyte esterase enzyme activity units ranged from 0 to 60% in both groups of samples. Further analysis of the comparison between the types of organisms cultured and the inhibition of the enzyme activity units by ebelactone is shown in Table IV. There were varying degrees of inhibition (range, 20% to 60%) in the uninfected samples. These same results were also found in the samples infected with gram-negative organisms (*E. coli, B. fragilis, Fusobacterium*). However, there was no inhibition of leukocyte esterase activity (range, 17.1 to 19.3) in the samples infected with gram-positive organisms (group B streptococcus, enterococci). These results were found to be statistically significant. The presence and ranges of inhibition were found to be similar in the samples with organisms $>10^2$ cfu/ml.

Comment

Despite the continuing seriousness of acute chorioamnionitis, which produces major morbidity in both mother and neonate, no optimal diagnostic findings currently exist. All attempts to improve our ability to diagnose this entity have been unsuccessful to date.

We previously reported on the reliability of measuring leukocyte esterase activity by a simple nonquantitative dipstick assay to diagnose intraamniotic infection in term and preterm gestations.[5,6] Because the results of the dipstick assay, like those of the aerobic and anaerobic cultures, can sometimes be misleading or equivocal we suggested the use of an in vitro spectropho-

tometric assay of esterase activity to eliminate some confusion.[4] This assay is rapid (<10 minutes) and simple to perform. It requires only a spectrophotometer and the determination of change in absorbance after the addition of substrate and inhibitor, both of which are easily available.

At present, even if clinical chorioamnionitis is reliably diagnosed, most standard protocols call for empiric choices of broad-spectrum antibiotics for immediate therapy. These choices are often based on preexisting theoretic knowledge of the pathogens that can cause such infections and not on the identification of specific organisms from the patient. This latter information is usually obtained much later (24 to 48 hours) when culture results are available. The results of our preliminary study suggest that the different bacteria that cause chorioamnionitis may elicit the production of different and specific esterases in infected amniotic fluid as shown by the differences in the in vitro inhibition of this activity by ebelactone. Thus it may be possible to identify the causative organisms in chorioamnionitis by measuring the absence, presence, and degree of in vitro leukocyte esterase inhibition by ebelactone. This would allow the formulation of timely and directed management decisions even before culture results are available.

Smoking and the antioxidant ascorbic acid: Plasma, leukocyte, and cervicovaginal cell concentrations in normal healthy women

Jayasri Basu, PhD, Magdy S. Mikhail, MD, Patricia H. Payraudeau, MD, Prabhudas R. Palan, PhD, and Seymour L. Romney, MD

Bronx, New York

The influence of cigarette smoking on the plasma, leukocyte, and cervicovaginal cell ascorbic acid levels in 46 healthy smokers and healthy nonsmokers was investigated. Coded peripheral venous blood and cervicovaginal lavage specimens obtained after informed consent were analyzed simultaneously for their ascorbic acid content. The findings suggest that smoking affects the levels and distribution of ascorbic acid. In smokers ($n = 16$), the number of exfoliated cervicovaginal epithelial cells and leukocyte ascorbic acid levels was significantly higher ($p < 0.01$, $p < 0.05$, respectively) compared with nonsmokers ($n = 30$). In addition, cervicovaginal cell ascorbic acid, plasma reduced and total ascorbic acid levels were significantly lower ($p < 0.001$, $p < 0.01$, $p < 0.01$, respectively). The exfoliated epithelial cell ascorbic acid levels in nonsmokers was fourfold greater than that of leukocytes. The implications of these findings within the context of free radical–induced cellular pertubations in smokers are discussed. (Am J Obstet Gynecol 1990;163:1948-52.)

Key words: Cigarette smoking, vitamin C, lavage technique, cell count, reduced ascorbic acid, total ascorbic acid, cervix cancer risk factors

The hypothesis that cigarette smoking is a causative factor in the development of cervical cancer has been evaluated by numerous investigators in case-control and cohort studies.[1-4] Epidemiologic studies suggest smoking to be an independent risk factor. The association between smoking and cancer of the cervix is seen to persist even after controlling for other known risk factors (e.g., multiple sexual partners, early age at first intercourse, or socioeconomic status).[5] Studies focused on the constituents of tobacco and its principal metabolites report that tobacco smoke contains mutagens and carcinogens and generates free radicals. These carcinogenic products are thought by some to act as initiators or promoters of the carcinogenic process.[6-8] Other studies revealed increases in mutagenic substances in cervical mucus of healthy women who are smokers.[9, 10] Although the deleterious effects of smoking are recognized and smoking is considered a risk factor for the development of cervical cancer,[1-11] the mechanism(s) whereby smoking exerts its carcinogenic effect(s) still remains obscure.

We have been investigating the role of nutrition in the pathogenesis of cervical cancer. A focus of our studies has been to delineate objective indices as a "risk profile" specifically correlated with cervical precancer states.[12-14] We previously determined the effect of smoking on the plasma levels of various nutrients in normal healthy women[15, 16] and those with cancer of the cervix.[12-14] The effects of smoking and human papillomavirus on plasma ascorbic acid and β-carotene levels in women with abnormal Papanicolaou smears were examined.[17] The findings of this investigation focus attention on a number of significant interactions triggered by cigarette smoking in apparently normal healthy women. Significant alterations in both the concentrations and distribution of plasma, leukocyte, and cervicovaginal cell ascorbic acid levels were noted in smokers.

Material and methods

Subject recruitment. Normal healthy women who attended the Women's Health Center of the Bronx Municipal Hospital Center in New York City for routine visits between August 1988 and March 1990 were asked to participate in the study. The study protocol was approved by the institutional review board. Forty-six women with two consecutive negative Papanicolaou smears who had normal regular menstrual cycles of ap-

6/6/24753

proximately 28 days, had no known gynecologic disorders, and were not using oral contraceptives or vitamin supplements were enrolled into the study. Subjects were not menstruating on the day samples were obtained. Peripheral venous blood and cervicovaginal lavage samples, collected by described methods,[14] were obtained from each participant with informed consent. Coded samples were transported to the laboratory promptly for ascorbic acid analyses. A self-administered study questionnaire including questions regarding age, parity, date of last menstrual period, contraceptive practices, and smoking history (the number of cigarettes smoked per day and years of smoking) was recorded. No dietary restrictions were imposed. However, on the morning samples were obtained the breakfast intake before the clinic visit was noted.

Analyses of ascorbic acid. Blood samples were collected in heparinized tubes. Plasma, leukocyte, and cervicovaginal cell ascorbic acid levels were determined promptly the same day the samples were collected without knowledge of the women's smoking or dietary status. Plasma was separated by centrifugation. Equal amounts of 0.9% sodium chloride were added to each tube and the leukocytes were removed by Ficoll method.[18] The total Ficoll layer was collected and centrifuged to obtain the leukocyte pellet. A known volume of the cervicovaginal lavage specimen was centrifuged to obtain a cervicovaginal cell pellet. To each of the known volumes of plasma, leukocyte, and cervicovaginal cell samples, 10% trichloroacetic acid was added. The plasma samples were thoroughly mixed. Leukocyte and cervicovaginal cell samples were additionally homogenized with a Polytron homogenizer. Each of the tubes containing the various samples was immersed in ice for 10 minutes and then centrifuged. The acidified supernatants were used to determine the levels of reduced and total ascorbic acid spectrophotometrically.[12]

Each assay was done in duplicate. Standard samples for both reduced and total ascorbic acid were analyzed simultaneously each day. The daily variation in standard ascorbic acid assays was less than 1%. The variation between duplicate samples, run simultaneously, was also less than 1%. Plasma reduced and total ascorbic acid levels are expressed as mg/dl. Leukocyte and cervicovaginal cell total ascorbic acid levels are expressed as micrograms per 10^6 cells. The lower limits of detection for the spectrophotometric methods for plasma reduced and total, leukocyte, and cervicovaginal total ascorbic acid levels were 50 mg/ml, and 0.01 $\mu g/10^6$ cells, respectively.

Leukocyte and cervicovaginal cell count. To a known volume of leukocyte suspension after Ficoll separation, or a cervicovaginal cell suspension, an equal volume of 2% Trypan blue solution was added. Each of the mixtures was dispensed onto a Neubeuer Hemacytometer. The cells distributed in the four corner squares were counted. Cell counts are expressed as number of cells $\times 10^6$ per milliliter.

Table I. Age, leukocyte, and cervicovaginal cell counts of smokers versus nonsmoker women

Group	*Age (yr)*	*Leukocyte count ($\times 10^6$ cells/ml)*	*Cervicovaginal cell count ($\times 10^6$ cells/ml)*
Smokers	32.5 ± 7.2 (n = 16)	11.64 ± 9.03 (n = 16)	1.24 ± 1.27 (n = 16)
Nonsmokers	28.0 ± 6.3 (n = 30)	14.71 ± 5.80 (n = 22)	0.58 ± 0.41 (n = 30)
p Value*	NS	NS	<0.01

Figures in parentheses indicate the number of subjects. Results are mean ± SD. Smokers on an average smoked 12.9 ± 9.5 cigarettes per day for 11.8 ± 7.6 years.

*By Student's t test.

Statistical analyses. The study code was broken in March 1990. Student's t test was applied to determine any association between the various study parameters: plasma reduced ascorbic acid, plasma total ascorbic acid, leukocyte total ascorbic acid, cervicovaginal cell total ascorbic acid and cervicovaginal cell and leukocyte count and (1) smoking, (2) phase of the menstrual cycle (women with last menstrual period ≤14 or >14 days), (3) methods of birth control (women not using any method versus those using barrier methods of birth control), and (4) breakfast intake (women who had or did not have breakfast on the day of sample collection).

Results

Sixteen of the 46 women in the study were smokers. Smokers on an average smoked 12.9 ± 9.5 cigarettes per day for 11.8 ± 7.6 years. The numbers of cigarettes smoked and the years of smoking varied from 2 to 35 per day and 4 to 25 years, respectively. Blood samples of eight nonsmoker women were obtained in amounts inadequate for leukocyte separation. The number of leukocytes and cervicovaginal cells of both smoker and nonsmoker subjects ranged from 1.14 to 32.4 and 0.1 to 4.64 $\times 10^6$ cells per milliliter, respectively. The ages of study subjects ranged from 18 to 44 years. The plasma reduced and total ascorbic acid, and leukocyte and cervicovaginal total ascorbic acid levels of all women in the study ranged from 0.18 to 0.917 mg/dl, 0.261 to 1.054 mg/dl; 0.073 to 0.554 $\mu g/10^6$ cells, and 0.01 to 1.797 $\mu g/10^6$ cells, respectively.

Table I compares the mean age, leukocyte, and cervicovaginal cell counts in smoker versus nonsmoker women. A significantly higher number of exfoliated cervicovaginal epithelial cells was observed in smokers. The cervicovaginal cell count of the smokers ranged

Table II. Distribution of plasma reduced and total, and leukocyte and cervicovaginal cell total ascorbic acid concentrations of smokers versus nonsmoker women

Group	*Plasma reduced ascorbic acid (mg/dl)*	*Plasma total ascorbic acid (mg/dl)*	*Leukocyte total ascorbic acid ($\mu g/10^6$ cells)*	*Cervicovaginal cell total ascorbic acid ($\mu g/10^5$ cells)*
Smokers	0.441 ± 0.235 (n = 16)	0.557 ± 0.218 (n = 16)	0.249 ± 0.146 (n = 16)	0.350 ± 0.378 (n = 16)
Nonsmokers	0.610 ± 0.190 (n = 30)	0.707 ± 0.170 (n = 30)	0.197 ± 0.092 (n = 22)	0.828 ± 0.546 (n = 30)
p Value*	<0.01	<0.01	<0.05	<0.001

Figures in parentheses indicate the number of subjects. Results are mean ± SD. Smokers on an average smoked 12.9 ± 9.5 cigarettes per day for 11.8 ± 7.6 years.

*By Student's t test.

from 0.01 to 4.64 × 10^6 cells per milliliter (median, 0.71 × 10^6). The cell counts of the nonsmokers ranged from 0.16 to 1.96 × 10^6 cells per milliliter (median, 0.46 × 10^6). The mean age and leukocyte count of the two study groups were comparable.

Table II compares the reduced and total plasma ascorbic acid levels, leukocyte, cervicovaginal cell total ascorbic acid levels of smokers versus nonsmoker healthy women. In smokers plasma reduced and total cervicovaginal cell total ascorbic acid levels were significantly lower, but the leukocyte total ascorbic acid level was significantly higher compared with the nonsmoker group. Because of the small sample size of smokers, statistical analysis to determine the effect of the number of cigarettes smoked times duration of smoking on the various study parameters could not be evaluated. The plasma ascorbic acid values analyzed by two separate procedures were found to be highly correlated (R = 0.55, p = 0.0001) and of similar magnitude.

The breakfast intake of each subject attending the morning clinics was analyzed. A total of 70% of the study population did not have any breakfast. Of those who had breakfast, 17% had only a cup of coffee, and two of the nonsmokers and two smokers had orange juice. The remaining subjects reported eating either one of a combination of the following: egg, toast, hamburger, hotdog, or French fries. All parameters studies were found to be comparable among women who ate or did not eat breakfast on the day of the clinic visit.

None of the study subjects used oral contraceptives. Subjects were not using any methods or were using barrier methods of birth control; when compared between these two groups the various study parameters were not statistically different. With regard to the menstrual cycle, there were 25 subjects in the follicular phase and 21 subjects in the luteal phase. The number of leukocyte and cervicovaginal cell counts of women in the follicular and luteal phases of the menstrual cycles was comparable ($p > 0.05$). In addition, ascorbic acid levels in the plasma, leukocytes, and cervicovaginal cells were not statistically different between women in the follicular versus luteal phase of the menstrual cycle.

Comment

This is the first study to report the levels of ascorbic acid simultaneously determined in plasma, leukocytes, and cervicovaginal cells in normal healthy women. Several noteworthy observations are apparent: (1) The exfoliation of cervicovaginal epithelial cells in smokers is significantly increased; (2) compared with leukocytes, the ascorbic acid level of exfoliated epithelial cells in nonsmokers is slightly higher; (3) in smokers, the difference in leukocyte and cervicovaginal cell ascorbic acid levels is markedly diminished; (4) leukocyte ascorbic acid level in smokers is significantly higher than in nonsmokers; (5) both plasma reduced and total ascorbic acid levels in smokers are significantly lower. The timing of the peripheral venous blood sample and cervicovaginal lavage sample collection with respect to the menstrual cycle of recruited subjects did not have any effect on any study parameters, indicating that the changes observed in this study were independent of menstrual cycle variations. Similarly, neither breakfast intake of the volunteer participants nor the method of birth control practiced was found to influence any of the study parameters. Smoking was the only variable that emerged as an influence on both the levels of ascorbic acid and exfoliation of cervicovaginal cells. Two separate assay procedures were used to determine the plasma reduced and total ascorbic acid levels. The plasma vitamin concentrations were found to be highly correlated and of equal magnitude. This suggests that ascorbic acid remains predominantly in the reduced state in normal healthy women.

Cancer prevention as an achievable goal challenges cancer research and has attained high priority. There is a substantial association between deficiency of dietary constituents and the incidence of certain malignancies.[19-21] Specific essential nutrients are hypothesized to reduce the cancer risk by neutralizing mutagens and

carcinogens, by quenching free radicals generated from various sources, or by augmenting the immune response.[6-8, 22, 23] Dietary substances with these attributes are vitamins A, C, E, β-carotene, and selenium.[24]

Biochemical evaluation of nutritional status is more precise and objective than dietary, clinical, or anthropometric assessments. In earlier investigations we assessed both dietary intake and plasma ascorbic acid levels in high-risk populations for cervix cancer.[12, 25] The results of this study confirm our earlier observations of significantly lower plasma reduced and total ascorbic acid levels in smokers (Table II) and is consistent with other investigators.[15, 26, 27] In peripheral blood, ascorbic acid has been shown to be highly liable and is partitioned between plasma and leukocytes according to the host's metabolic demands.[28] The leukocyte content of vitamin C is greater than the concentration in most other tissues, including plasma.[29]

Polymorphonuclear leukocytes are reported to generate reactive oxidants during phagocytosis.[30] Cervicovaginal cells may be at increased risk of free radical exposure as a consequence of smoke-induced carcinogens present in cervical mucus, and/or human papillomavirus infection, or both. An unexpected finding of this investigation is the high ascorbic acid levels of exfoliated epithelial cells in nonsmokers: the concentration was slightly higher than that of the leukocytes. The cervicovaginal cell ascorbic acid levels in smokers, although significantly lower than in nonsmokers, however, are greater than the leukocyte levels (Table II). Hence we suggest that in normal healthy women the antioxidant nutrient ascorbic acid is preferentially accumulated in both the leukocytes and cervix, tissues that are increasingly at risk of exposure to free radical damage.

There are several reports of the immuno-enhancing potential of ascorbic acid. Ascorbic acid deficiency in humans has been associated with impaired ingestion of microorganisms by polymorphonuclear leukocytes. The defective phagocytosis has been corrected by the administration of vitamin C.[31] Supplementation of ascorbic acid in healthy males resulted in a statistically significant increase in the serum levels of IgA, IgM, and C3 complement.[32] An elevation in macrophage ascorbic acid levels in smokers has also been reported.[33]

It is now established that hydrocarbon carcinogens absorbed from the pulmonary system are transmitted through the circulation to distant tissues and organs in cigarette smokers.[34] Nicotine and cotinine are selectively accumulated in the cervical mucus against a serum concentration gradient.[35] It is also reported that particulates found in cigarette smoke induce the release of a macrophage-derived chemotactic factor that attracts polymorphonuclear leukocytes. During phagocytosis, collagenase, elastase, or both are released from neutrophils with a concomitant increase in the production of free radical, "superoxide anions."[31, 36]

The higher content of leukocyte ascorbic acid in smokers despite a concentration gradient of significantly lower plasma reduced and total ascorbic acid levels suggests a preferential accumulation of the vitamin (Table II). The increment implies a requirement of the essential micronutrient by the leukocytes in smokers, possibly to enhance the host's defense mechanism. However, the comparatively lower cervicovaginal cell ascorbic acid levels in smokers (Table II) may reflect the increased utilization of ascorbic acid by the cervical tissue, counteracting the injurious effects of smoke-induced carcinogens and oxidative pertubations.

In this study increased numbers of exfoliated cervicovaginal cells were harvested from the lavage samples of smokers (Table I). This result is consistent with our previously reported finding.[14] Accumulation of polymorphonuclear leukocytes and macrophages in cervical tissue with a concomitant increase in the release of elastase and collagenase during phagocytosis may be responsible for decreasing the cohesiveness of cervicovaginal epithelial cells in smokers, resulting in increased exfoliation. Alternatively, smoking may induce an acceleration in the mitotic activity of cervicovaginal epithelial cells and expedite the exfoliation of cervical epithelium. We hypothesize that in cigarette smokers, inadequate concentrations of ascorbic acid and other antioxidants in cervical tissue render it susceptible to free radical damage. If deficiencies of antixodant nutrients in conjunction with excess production of free radicals persists for a prolonged period of time, cellular damage may ensue. Such events occurring over time in association with an altered immune response, and in the presence of other cervix cancer risk factors, may be an important component of the oncogenic process.

Short-term effects of smoking on the pharmacokinetic profiles of micronized estradiol in postmenopausal women

Denise Lee Cassidenti, MD, Ariel G. Vijod, MS, Marcela A. Vijod, BS, Frank Z. Stanczyk, PhD, and Rogerio A. Lobo, MD

Los Angeles, California

Because smoking is associated with an increased risk for osteoporosis, yet a decreased risk of endometrial carcinoma, a state of relative hypoestrogenism induced by smoking has been suggested. However, because previous data are unclear and do not reflect current trends in smoking intensity and estrogen prescriptions, we examined the estrogen profiles of postmenopausal women, by smoking status, both before and after oral micronized estradiol. Baseline levels of estrone, estradiol, estrone sulfate, and estrone glucuronide were similar in nonsmokers and smokers, but unbound (non-sex-hormone-binding-globulin–bound) estradiol was significantly lower in smoking women ($p < 0.05$) and sex-hormone-binding-globulin–binding capacity was higher ($p < 0.001$). After 1 or 2 mg of micronized estradiol, estrone and estradiol serum profiles were similar but unbound estradiol was significantly lower in women who were smokers ($p < 0.05$). Serum estrone glucuronide rose with treatment but was indistinguishable in nonsmokers and smokers. However, maximum changes in serum estrone sulfate were greater in smokers after administration of estrogen, suggesting a hepatic effect. Urinary estrone glucuronide levels increased after 8 hours of oral estrogen but were similar in nonsmokers and smokers with the two doses. It appears that even moderate smoking, as studied here, induces significant changes in hepatic estrogen metabolism and is best reflected by alterations in serum estrone sulfate and sex-hormone-binding-globulin–binding capacity that result in decreased serum unbound estradiol. However, these changes do not appear to require increasing the estrogen dosage to achieve physiologic levels of estrogen in postmenopausal smokers. (Am J Obstet Gynecol 1990;163:1953-60.)

Key words: Smoking, estrogen status, postmenopausal women, pharmacokinetic profiles

Cigarette smoking has been associated with an increased risk of osteoporosis[1] but a decreased risk of endometrial cancer[2] in postmenopausal women. MacMahon et al.[3] first reported decreased urinary estrogen levels in the luteal phase of premenopausal women who were smokers. Thus it has been suggested that smoking causes a relative hypoestrogenism that explains the increased risk of osteoporosis but decreased risk of endometrial cancer.

Jensen et al.[4,5] attempted to address the question directly and have reported lower estrone levels in smoking postmenopausal women after they received hormonal replacement. However, the baseline estrogen status of nonsmokers and smokers was not significantly different. Moreover, the women in this study received a mixture of sex steroids, including a progestin, and the effects were most marked only in women who received high doses of estrogen.

Because it appeared likely that any effects of smoking on estrogen status would be related to the amount and intensity of smoking, we thought it was important to examine this issue in women who were only moderate smokers to establish the clinical relevance of this association in our patient population. To study this issue and after review of the previous studies, we reexamined this issue and sought to determine: (1) the baseline estrogen status of postmenopausal women who smoke, (2) estrogen levels after smoking in women who ingest only moderate doses of estradiol, (3) the possible mechanisms explaining the postulated altered estrogen metabolism in smokers, and (4) whether an increased dose of estrogen would be required in smokers to achieve physiologic hormone replacement.

Material and methods

Subjects. Volunteers were 25 healthy postmenopausal women who had not received hormonal replacement for at least 2 weeks. All women had been postmenopausal for at least 2 years before the study. The women were healthy and had no history of cancer or chronic illnesses. Twelve women were nonsmokers, and 13 women were long-term smokers who reported

Table I. Characteristics of patient population

	n	*Age (yr, mean ± SE)*	*Ponderal index (mean ± SE)*
Estrace 1 mg			
Nonsmokers	9	58.4 ± 2.2	11.6 ± 0.1*
Smokers	10	58.7 ± 1.6	12.2 ± 0.1
Estrace 2 mg			
Nonsmokers	3	56.7 ± 3.3	11.7 ± 0.1*
Smokers	3	58.7 ± 2.0	12.5 ± 0.1

*$p < 0.01$.

smoking an average of 11.6 ± 1.4 cigarettes per day (range, 6 to 20 cigarettes per day).

Protocol. All patients were studied at 8 AM after eating a light breakfast to increase the absorption of the oral micronized estradiol. The women (nonsmokers and smokers) were randomly assigned to receive either 1 or 2 mg of micronized estradiol (Estrace, Mead Johnson, Evansville). Smokers were instructed to smoke a cigarette of their own brand immediately after ingesting the micronized estradiol and then continue to smoke at normal intervals during the remaining 8 hours. Blood samples were drawn at baseline, 1, 2, 4, and 8 hours after micronized estradiol was ingested to determine the acute hepatic effects and pharmacokinetic profiles of oral ingestion. A random urine sample was collected at the start of the study followed by an 8-hour collection to assess urinary excretion. All urine samples were immediately stored at −20° C. Sera samples obtained were separated and stored at −20° C until assayed. All samples were assayed for estrone, estradiol, sex-hormone-binding-globulin–binding capacity, unbound (non-sex-hormone-binding-globulin–bound) estradiol, and the serum estrogen conjugates estrone glucuronide and estrone sulfate, which reflect hepatic metabolism. Urine was analyzed for estrone glucuronide and creatinine levels.

Assays. The assays for estradiol, sex-hormone-binding-globulin–binding capacity, and unbound estradiol have been previously validated and described.[6-9] For the purposes of this study, these assay systems were developed and validated. Estrone was measured by means of a specific estrone radioimmunoassay (RIA) that does not require a chromatographic step before quantitation. To 1 ml of serum, approximately 1000 dpm of tritiated estrone (DuPont NEN Research Products, Boston; specific activity, 42 Ci/mmol) in 0.1 ml of assay buffer [0.1 mol/L sodium phosphate, pH 7.0; 0.15 mol/L sodium chloride; 0.1% (wt/vol) Knox unflavored gelatin; 0.1% (wt/vol) sodium azide] is added as an internal standard to monitor procedural losses and incubated at 37° C for 30 minutes. The serum is extracted twice with 5 ml of ethyl acetate/hexane (4 : 6, vol/vol), and the combined organic phases are evaporated under nitrogen. The residue is reconstituted in 10% ethanol in assay buffer (vol/vol). The RIA is performed with a highly specific antiserum (Pantex, Santa Monica) directly against estrone. The antiserum exhibited a 0.14% cross-reaction with estradiol.

These reliability criteria were determined for the estrone RIA. The sensitivity of the assay (defined as the smallest amount of estrone per RIA tube that reduces the number of counts per minute of tritiated estrone bound at zero mass by 2 SDs) was 3.9 pg per tube or 15 pg/ml. Accuracy was determined by adding known amounts of authentic estrone to pooled serum. Linear regression analysis performed to compare estrone values measured in pools versus the amount of estrone added revealed a correlation coefficient of 0.99. Parallel experiments comparing the current assay with the previous validated estrone assay, requiring column chromatography,[10] were performed and showed equivalent values with an average difference of 5 pg/ml. The interassay coefficient of variation for estrone was 14%.

Estrone glucuronide was measured in an aliquot of 0.6 ml of serum combined with an internal standard of approximately 100 dpm of tritiated estrone glucuronide (Amersham Laboratories, Buckinghamshire, England; specific activity, 12.6 Ci/mmol) dissolved in 0.1 ml of 0.2 mol/L sodium phosphate buffer, pH 6.8, to monitor procedural losses and incubated at 37° C for 30 minutes. After extraction of unconjugated steroids, 2 ml of the phosphate buffer is added to the aqueous layer. To each sample 500 units of β-glucuronidase, type VIIA from *Escherichia coli* (Sigma Chemical Co., St. Louis) in 0.1 ml of the phosphate buffer is added and incubated overnight at 37° C. The hydrolyzed estrogens are extracted twice with 5 ml of ethyl acetate/hexane (4 : 6, vol/vol). After evaporating the organic solvents, the extract is reconstituted and the estrone is measured as described above. All values were corrected for molecular weight.

The following reliability criteria were determined for the estrone glucuronide RIA. The sensitivity of the assay was 45 pg/ml. Accuracy experiments revealed a correlation coefficient of 0.99. The specificity of the β-glucuronidase for conjugated estrone was 0.27%. The interassay coefficient of variation was 9.3%.

Estrone sulfate was measured on the basis of a modification of the procedure described by Platia et al.[11] To a 0.2 ml aliquot of serum, approximately 1000 dpm of tritiated estrone sulfate (DuPont NEN Research Products; specific activity, 60 Ci/mmol) in 0.1 ml of sodium acetate buffer, pH 5, is added as an internal standard to monitor procedural losses and is incubated at 37° C for 30 minutes. The samples are extracted twice with 5 ml of ethyl acetate/hexane (4 : 6, vol/vol) to remove unconjugated steroids. The aqueous phases are combined and deproteinated with 2 ml of methanol. After

Table II. Baseline estrogen status of nonsmoking and smoking postmenopausal women

	Estrone (pg/ml)	*Estradiol (pg/ml)*	*Unbound estradiol (pg/ml)*	*Estrone glucuronide (ng/ml)*	*Estrone sulfate (ng/ml)*
Nonsmokers ($N = 12$)	64 ± 8	19 ± 3	8.6 ± 1.4	0.193 ± 0.03	1.58 ± 0.25
Smokers ($N = 13$)	63 ± 6	14 ± 1	4.9 ± 0.6*	0.199 ± 0.03	1.65 ± 0.21

*$p < 0.01$.

the mixture is spun in a vortex, the protein pellet is removed by centrifugation, and the methanol is evaporated under nitrogen at 40° C. The residue is reconstituted in 2 ml of the acetate buffer, and 6.7 units of arylsulfatase type VIII from abalone entrails (Sigma Chemical Co.) is added, followed by an overnight incubation at 37° C. The hydrolyzed estrogens are extracted twice with 5 ml of ethyl acetate/hexane (4:6, vol/vol) mixture. After the organic solvents are evaporated, the extract is reconstituted and the estrone is measured as described earlier. All values were corrected for molecular weight and for estrone glucuronide procedural losses.

The following reliability criteria were determined for estrone sulfate RIA. The sensitivity of the assay was 160 pg/ml. The average efficiency of hydrolysis was 85% with an overall recovery of 71%. Parallelism was established by serial dilution of pooled serum. The resulting curve was parallel to the corresponding standard curve. Specificity of the arylsulfatase enzyme for estrone glucuronide was 8%. The interassay coefficient of variation was 11%. Assays for urinary estrone glucuronide and creatinine were performed as previously described.[12]

Statistical analyses were done between groups with paired and unpaired t tests and logarithmic transformation. All data are reported as mean ± SE.

Results

Table I depicts the characteristics of our patients. Body habitus is reported by the ponderal index, which is height (inches) divided by the cube root of the weight (pounds). Patients receiving Estrace 1 or 2 mg were matched for age. However, on the basis of ponderal indices, the nonsmokers were significantly heavier than the smokers in both groups ($p < 0.01$).

Baseline estrogen status of nonsmokers ($n = 12$) and smokers ($n = 13$) is depicted in Table II. There were no differences in levels of estrone, estradiol, estrone glucuronide, or estrone sulfate. However, baseline levels of unbound estradiol were significantly lower in smokers than in nonsmokers (4.97 ± 0.62 vs 8.56 ± 1.4 pg/ml, $p < 0.01$).

With Estrace 1 mg, nonsmokers and smokers had similar estradiol and estrone levels for 8 hours after ingestion (Fig. 1). Peak levels averaged 200 pg/ml for estrone and 40 pg/ml for estradiol in both groups. However, levels of unbound estradiol, although similar in nonsmokers and smokers after 1 hour, were significantly lower in smokers at 8 hours (13.3 ± 1.4 vs 25.9 ± 4.1 pg/ml, $p < 0.02$). Serum estrone glucuronide peaked at two hours and decreased rapidly thereafter. Conversely, estrone sulfate showed a gradual rise that reached maximum levels at 4 hours (20 ng/ml) and these levels were sustained thereafter. No statistical differences were observed for these serum conjugates in nonsmokers and smokers.

In patients who received Estrace 2 mg, smokers had higher levels of estrone compared with nonsmokers at 1 hour (200 ± 34.6 vs 99.3 ± 9.1 pg/ml, $p < 0.05$) (Fig. 2). The same trend was observed with estradiol but was not statistically significant. Over the entire 8 hours, values of estrone and estradiol were not significantly different in nonsmokers and smokers and peaked at levels of 350 and 50 pg/ml, respectively. Unbound estradiol was not significantly different at baseline but was significantly lower in smokers than in nonsmokers, both at 4 hours (14.9 ± 1.5 vs 29.8 ± 4.6 pg/ml, $p < 0.05$) and at 8 hours (16.9 ± 1.5 vs 36.9 ± 11.5 pg/ml, $p < 0.05$). Serum estrone glucuronide levels showed a rapid increase in smokers but were not statistically different from responses of nonsmokers. Serum estrone sulfate levels were also higher in smokers than in nonsmokers, but these values were only of borderline significance ($p < 0.06$).

Sex-hormone-binding-globulin–binding capacity was significantly higher in smokers compared with nonsmokers in both treatment groups: Estrace 1 mg (smokers vs nonsmokers, 136.7 ± 8.2 vs 89.8 ± 8.2 nmol/L; $p < 0.0001$) and Estrace 2 mg (smokers vs nonsmokers, 191.3 ± 13.2 vs 61.6 ± 8.3 nmol/L, $p < 0.0001$) (Fig. 3). This 35% to 68% difference in sex-hormone-binding-globulin–binding capacity between smokers and nonsmokers could not be accounted for solely on the basis of body mass because there was only a 5% to 7% difference in ponderal index between the two groups. As expected, there were no changes with 8 hours of treatment (data not shown).

To better analyze estrogen metabolism, we examined the maximum changes in the hepatic markers, serum

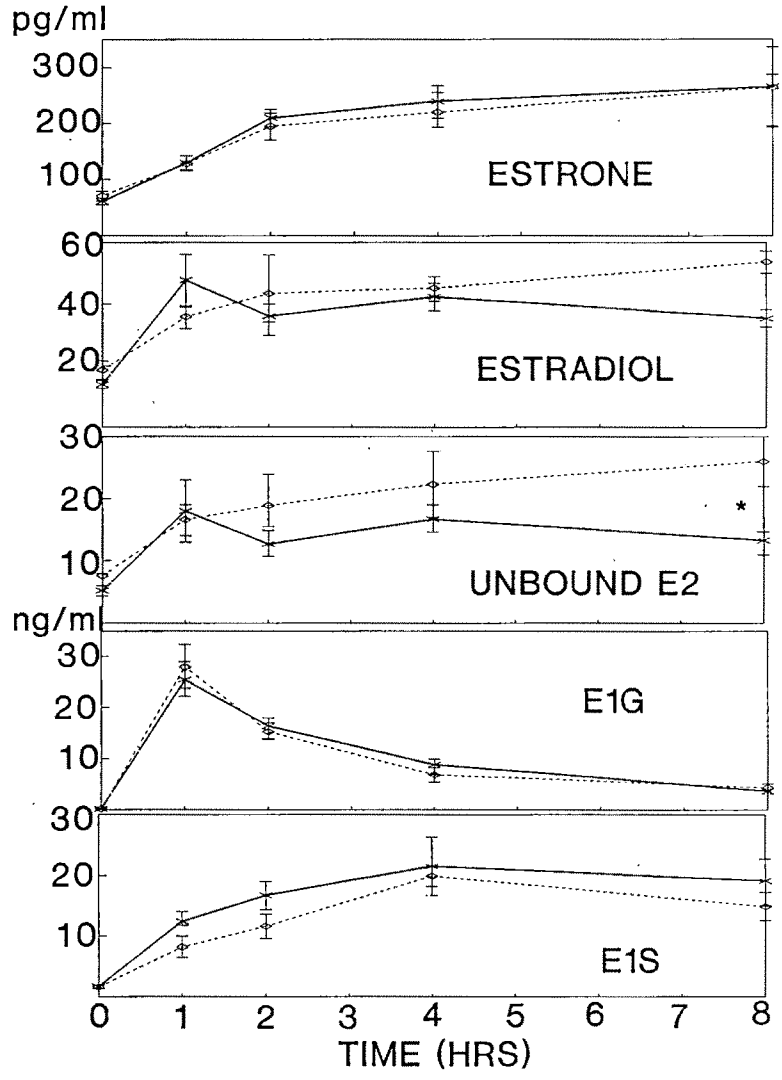

Fig. 1. Pharmacokinetic profiles in women receiving Estrace 1 mg. Nonsmokers *(dotted line)* are compared with smokers *(solid line)*. *Asterisk*, $p < 0.02$.

estrone glucuronide and estrone sulfate, from baseline to peak. When the groups receiving Estrace 1 mg and 2 mg were compared, the maximum changes in levels of estrone glucuronide were not statistically different in nonsmokers and smokers (Fig. 4). However, a trend was observed with Estrace 1 mg; the maximum changes in estrone sulfate were higher in smokers than in nonsmokers but was not statistically significant. In the 2 mg group, this difference in estrone sulfate was statistically significant (24.4 ± 4.2 vs 8.7 ± 0.2; $p < 0.05$).

Concentrations of urinary estrone glucuronide (micrograms per gram of creatinine) in the patients are shown in Fig. 5. At baseline, urinary estrone glucuronide was virtually undetectable and was not different in nonsmokers and smokers. Eight hours after oral ingestion, estrone glucuronide levels rose significantly. With Estrace 1 mg, the values were similar for nonsmokers (729 ± 110 μg estrone glucuronide per gram of creatinine). With Estrace 2 mg, no statistical difference was observed between nonsmokers (1470.7 ± 264 μg estrone glucuronide per gram of creatinine) and smokers (1829.3 ± 855 μg estrone glucuronide per gram of creatinine).

Comment

There were no differences in baseline levels if estrone, estradiol, and the conjugates, estrone sulfate and estrone glucuronide, between untreated postmenopausal nonsmokers and smokers. However, baseline unbound estradiol was significantly lower in postmenopausal women who smoked. This could be firmly established only when all women participating in this study were evaluated together (both treatment groups at baseline). This finding is most likely the result of increased sex-hormone-binding-globulin–binding capacity in the women who smoked. Thus, even though our

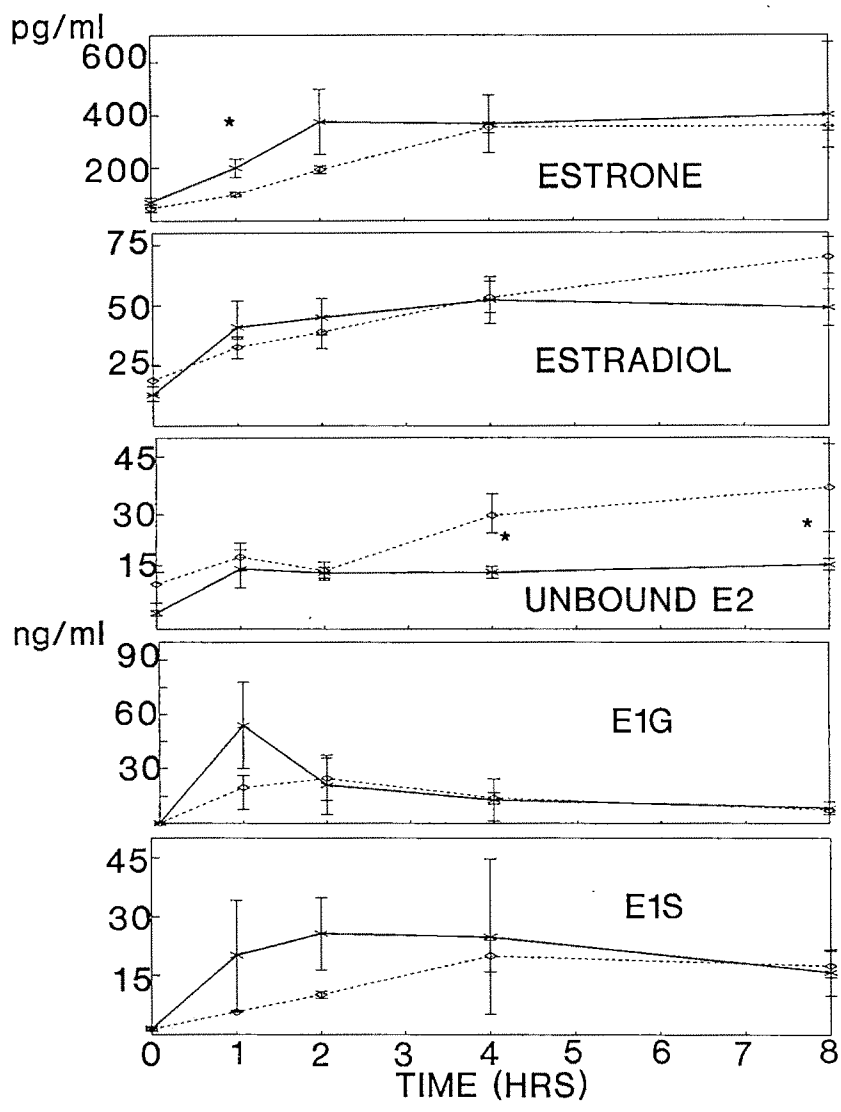

Fig. 2. Pharmacokinetic profiles in women receiving Estrace 2 mg. Nonsmokers *(dotted line)* are compared with smokers *(solid line)*. *Asterisk*, $p < 0.05$.

patients were only moderate smokers (smoking an average of 11.6 ± 1.4 cigarettes per day), the findings in estrogen status were of significance. This degree of smoking is reflective of current smoking trends in California.[13] Studies done by the National Health Interview Survey over the last 10 years have shown a steady decline in smoking prevalence in the United States from 36.7% in 1974 to 30.4% in 1985. A decline was also seen when men and women were analyzed separately. Women showed a steady decline in smoking of 0.33% per year.[14]

With use of 1 mg oral micronized estradiol, levels of estrone and estradiol were not significantly different. Increasing the dose of estradiol to 2 mg did not significantly change these profiles. In comparison with our results, Anderson et al.,[15] who administered oral estradiol valerate, showed similar peak levels of estrone and estradiol. However, maximum levels in this study were seen at 4 hours and were noted to decline at 6 hours, whereas in our study estrone and estradiol levels were sustained. Although our levels of estrone sulfate are comparable to those previously reported,[15] our values for serum estrone glucuronide with oral estrogen are twofold to threefold higher than values reported by Siddle and Whitehead.[16] These differences in the measurements and pharmacokinetics of estrogen may be related to assay differences and the absorption characteristics of micronized estradiol.

Unbound estradiol was significantly lower in smokers after oral Estrace administration. This was more marked with Estrace 2 mg where significant changes occurred at 4 and 8 hours. The data on unbound estradiol, being reflective of biologically available estradiol, suggest that smokers have less biologically avail-

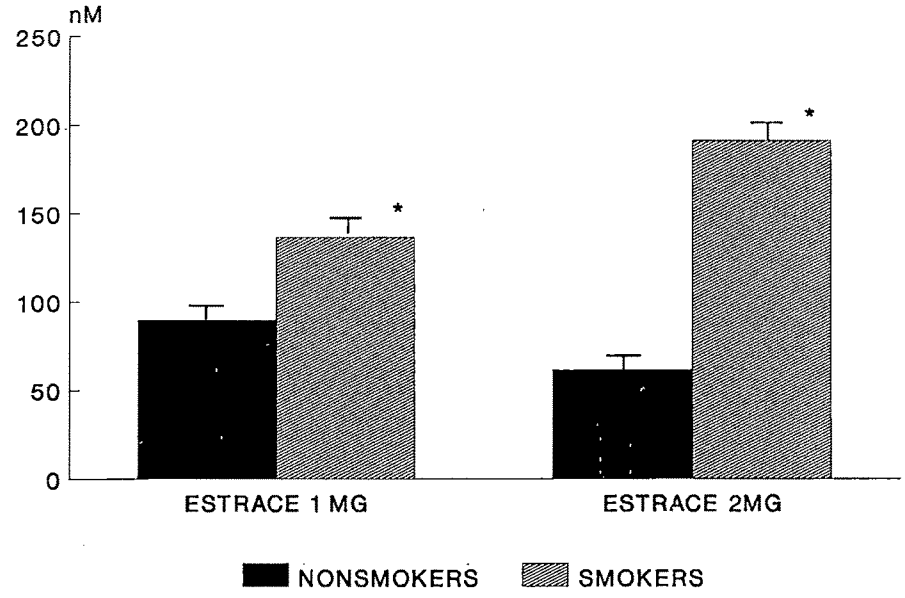

Fig. 3. Sex-hormone-binding-globulin–binding capacity in nonsmokers compared with smokers in the two treatment groups. *Asterisk*, $p < 0.0001$.

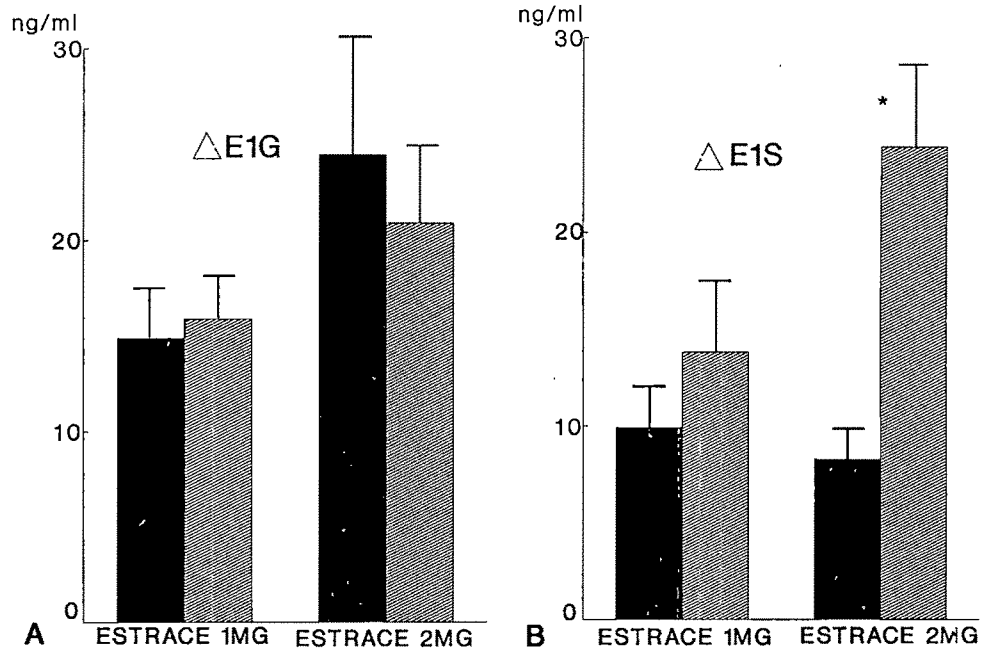

Fig. 4. Maximum changes from baseline in hepatic markers of estrogen metabolism with smoking. **A**, nonsmokers versus smokers. **B**, Estrone sulfate, nonsmokers versus smokers. *Black bars*, nonsmokers; *hatched bars*, smokers. *Asterisk*, $p < 0.05$.

able estradiol than nonsmokers. This supports data that implicated elevated free estradiol as a risk factor for endometrial cancer[17] and may explain the decreased incidence of endometrial carcinoma seen in smokers. The presence of lower biologically available estradiol also supports evidence that places smokers at a higher risk for osteoporosis.

Body weight is inversely related to sex-hormone-binding-globulin–binding capacity. Although groups matched for weight in this study would have been ideal, it is well known that smokers have lower body weights than nonsmokers and matching would have been difficult. Despite the differences in body weight, the large difference in sex-hormone-binding-globulin–binding

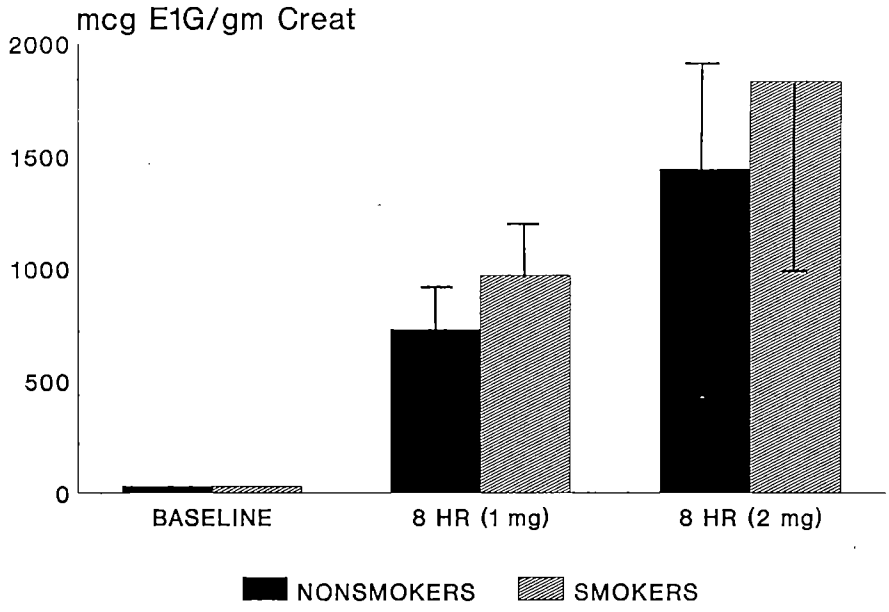

Fig. 5. Urinary estrone glucuronide in nonsmokers and smokers at baseline and in an 8-hour collection after administration of Estrace 1 or 2 mg.

capacity between smokers and nonsmokers is greater than what would be expected solely on the basis of increased body weight alone. Linear regression analysis showed only a loose correlation between sex-hormone-binding-globulin–binding capacity to ponderal index ($r = 0.43, p < 0.04$). This alone does not fully explain our data since baseline levels of unbound estradiol were similar in smokers and nonsmokers. Only after oral estrogen ingestion did unbound estradiol levels change. Sex-hormone-binding-globulin is known not to increase over this short period of time (8 hours).

Our data are similar to that of Jensen et al.,[4, 5] in which baseline levels of serum estrone and estradiol in untreated postmenopausal women were not statistically different. In this Danish study, differences in both estrone and estradiol levels were only observed when high doses of estrogen (4 mg of estradiol) were used. In the same study, the women received a mixture of sex steroids, including a progestin, norethisterone acetate, that may have influenced hepatic clearance.

Serum estrogen conjugates, as markers of hepatic metabolism, are important for the complete evaluation of the pharmacokinetic profiles of our patients. Smoking appears to increase hepatic metabolism in a dose-related manner, resulting predominantly in increased serum estrone sulfate. Because estrone glucuronide and estrone sulfate are hepatic products and significant changes in estrone sulfate were observed only with Estrace 2 mg and was of borderline significance with 1 mg, this suggested to us that the effect was dose-related. Several studies have examined changes in the estrogen conjugates estrone sulfate and estradiol sulfate after administration of various sex steroids.[18, 19] The rise in these conjugates has been shown to be dose-related[20] as we have demonstrated here. The relatively long half-life of estrone sulfate, because of its high affinity to albumin, resulted in higher levels that made changes easier to detect. Serum estrone glucuronide is cleared rapidly from the circulation and was not different between groups in this study.

Estrone glucuronide increased after administration of micronized estradiol but was cleared by the kidneys faster than estrone sulfate. No differences in the urinary levels of estrone glucuronide between the two groups were noted. Thus no direct effects of smoking on renal clearance could be demonstrated. We would have predicted that the rapid increase in hepatic metabolism would have also resulted in lowered estrone levels in addition to unbound estradiol, but we were unable to demonstrate this. Although this should be related to the intensity of smoking, no correlation could be found between the number of cigarettes smoked per day and the levels of estrone, estradiol or unbound estradiol.

Therefore we hypothesize that smoking increases hepatic metabolism leading to increases in sex-hormone-binding-globulin–binding capacity, estrone sulfate, and estrone glucuronide. The effects are most marked in the case of sex-hormone-binding-globulin–binding capacity. With estrogen treatment, changes in serum estrone sulfate were more marked than those of serum estrone glucuronide. The effects observed are related to the dose of estrogen ingested, with greater effects observed at higher doses. Only minmal differences in

estrone sulfate and estrone glucuronide were observed with Estrace 1 mg, and only when Estrace 2 mg was used were the observed effects significant.

Increased doses of estradiol would likely have resulted in more profound effects on estrogen metabolism than the doses studied here. However, because postmenopausal hormonal replacement usually does not exceed Estrace 2 mg, the effects of moderate smoking appear to be mild. Although differences do exist, on the basis of these data, these differences do not appear to be large enough to warrant increasing routine doses of estrogen replacement in postmenopausal women who smoke.

Oxytocin and vasopressin binding sites in human and bovine ovaries

Anna-Riitta Fuchs, DSc, Oliver Behrens, MD, Hanns Helmer, MD, Annette Vangsted, MD, Marina Ivanisevic, MD, Jamie Grifo, MD, PhD, Ciro Barros, PhD, and Michael Fields, PhD

New York, New York, and Gainesville, Florida

Human ovarian tissue and bovine ovarian stroma and follicles bound tritiated oxytocin and tritiated arginine vasopressin with similar affinity, whereas bovine corpora lutea bound tritiated oxytocin only. Competition for the binding of tritiated oxytocin by various agonists and antagonists was suggestive of receptor function. The number of oxytocin binding sites varied cyclically in all tissues. In bovine ovarian stroma and corpora lutea the concentrations were lowest on day 14 and highest on days 17, 19, and 21 after ovulation, with a striking peak in the luteal concentration on day 19. In human ovarian tissues the concentrations also were highest in samples obtained in late luteal phase. In large follicles the concentration of oxytocin binding sites was highest on the day of estrus and lowest on day 7. In bovine ovary the number of arginine vasopressin binding sites was ~50% lower than oxytocin binding sites and the cyclic variations were not significant. Human ovarian tissue had similar numbers of oxytocin and arginine vasopressin binding sites. Because bovine ovaries produce oxytocin and argine vasopressin the results suggest a paracrine or autocrine role for these neuropeptides in luteolysis and ovulation. Although their synthesis in human ovaries is still controversial the presence of binding sites suggests a physiologic role in the regulation of human ovarian function as well. (AM J OBSTET GYNECOL 1990;163:1961-7.)

Key words: Oxytocin, vasopressin, receptors, ovaries, corpora lutea, follicles

Oxytocin has been found in the corpora lutea of many species including cow,[1, 2] sheep,[3] pig,[4] rat,[5] deer,[3] human,[6] and cynomolgus monkey.[7] It is produced by the granulosa-derived large luteal cells[4, 8] and periovulatory granulosa cells.[4, 9, 10] The ability of oxytocin to affect luteal function has been demonstrated in several species including the ruminants[11, 12] and primates.[13] In species in which the uterus is essential for the regulation of corpus luteum life span, oxytocin is thought to act on the endometrium to cause the release of prostaglandin $F_{2\alpha}$[14] ($PGF_{2\alpha}$), which in turn acts on the corpus luteum to cause luteolysis.[15, 16] In species in which the influence of the uterus on luteal life-span is not significant (e.g., the primates), oxytocin may have a paracrine role in the regulation of ovarian function, acting on ovarian tissues to release $PGF_{2\alpha}$, which then diffuses into the adjacent luteal cells to cause luteolysis.[17] To determine the validity of such a hypothesis, we examined the binding of oxytocin to ovarian tissues because the presence of receptors is a prerequisite for oxytocin action. Arginine vasopressin is produced in the ovaries of some species,[5] and specific binding sites for arginine vasopressin have been found in other tissues of the female reproductive tract.[18, 19] We therefore examined the tissues also for the presence of arginine vasopressin binding sites.

Material and methods

Human subjects. Ovarian tissue was obtained from nine premenopausal women who had operations for the following nonmalignant causes: ovarian cysts (three cases), endometriosis (three), benign ovarian tumor (one), fibroids of the uterus (one), and hydrosalpinx (one). The contralateral ovary was used in all instances but one, and the tissue was histologically normal in all instances. All patients gave their consent and the project was approved by the Institutional Human Rights Committee. The tissues were kept on ice until the pathologists had examined the ovarian tissue and cut a portion of macroscopically normal tissue without the capsule and corpora lutea. The tissue was then wrapped tightly in foil and frozen at −70° to −80° C until assayed. Because insufficient tissue was available from individual patients to permit saturation analysis, tissues were pooled according to the stage in menstrual cycle

when the operation was performed. This was determined from the menstrual history and verified by histologic examination of the endometrium. The following pools were obtained: 1, proliferative phase, days 6 and 7 (two pools); 2, midcycle, days 14 to 18 (two pools); 3, late luteal phase, days 19 to 28 (one pool).

Animals. Eighteen Hereford cows from the herd of the Animal Science Department of the University of Florida were killed on days 7, 14, 17, 19, and 21 after behavioral estrus (three cows each day). The tissues were removed as quickly as possible, the ovaries were freed of peritoneum, large follicles and corpora lutea were dissected, and the stroma, follicles, and corpora lutea were frozen separately and kept at −70° to −80° C until assayed.

Tissue preparation. The tissues were homogenized in 10 mmol/L Tris buffer containing 3 mmol/L ethylenediaminetetraacetic acid, 0.5 mmol/L dithiothreitol, and 0.002% of a protease inhibitor, phenylmethylsulfonyl fluoride (Sigma, St. Louis). Four 5-second pulses with a Polytron tissue grinder (Brinkman, Westbury, N.Y.) with 30-second intervals were used followed by four up-and-down strokes with a hand-held glass tissue grinder (Kontes, Vineland, N.J.). All steps were performed in an ice bath. A crude membrane preparation precipitated between 1000 *g* (10 minutes) and 160,000 *g* (30 minutes) at 4° C was used to maximize binding. The membrane preparations were washed repeatedly in 3 mmol/L ethylenediaminetetraacetic acid buffer to dissociate all endogenous oxytocin or arginine vasopressin from their binding sites. This is an important step because corpora lutea may contain significant amounts of oxytocin, which would interfere with the receptor assay, because of the relatively low specific activity of the available tritiated oxytocin (37 mCi/mmol). Membranes were suspended in calcium-free Hanks physiologic salt solution for storage at −70° to −80° C in a concentration of 1 mg/ml.

Binding assay. The assay measures the total number of binding sites in the particulate membrane fractions. The final protein concentration was 1:1.5 mg/ml in the assay buffer; the total volume of 220 μl/tube was increased to 400 μl/tube when >330 μg protein per tube was used. The assay buffer consisted of 0.05 mol/L Tris maleate, 5 mmol/L manganese chloride, 0.002% phenylmethylsulfonyl fluoride, and 0.1% bovine serum albumin pH 7.4. The labeled ligands were tritiated oxytocin (specific activity, 37 mCi/mmol) and tritiated arginine vasopressin (specific activity, 57.8 mCi/mmol) from New England Nuclear (Boston). The assay conditions were as previously described[18, 19]: incubation with shaking for 60 minutes at 22° C terminated by adding 5 ml ice-cold buffer and rapid filtration through Whatman CF/F glass fiber filters using a cell harvester (Brandel, Gaithersburg, Md.). The unlabeled ligands (purity: >99% by high-performance liquid chromatography verified by capillary electrophoresis) were obtained from Bachem (Torrance, Calif.). Other peptides were obtained from Peninsula, and other chemicals were from Sigma.

Saturation analysis. Analysis was done by use of six to eight different concentrations of labeled ligand ranging from 10^{-10} to 10^{-8} mol/L. Nonspecific binding was determined in the presence of 1.1×10^{-6} mol/L concentration of unlabeled ligand. All assays were done in duplicate.

Displacement and competition assays. These were performed with pooled bovine ovarian stromal membranes prepared from tissues obtained on days 17 and 21 of cycle. The following agonists were used: oxytocin; arginine vasopressin; isotocin, a highly selective oxytocin agonist; 1-deamino-8-D-arginine vasopressin (ddAVP), a highly selective antidiuretic agonist; and two selective oxytocin antagonists, 1 deamino[2-D-tyrosine (O-ethyl)-8-ornithine]oxytocin RWJ (provided by Dr. D. W. Hahn, Ortho Pharmaceutical Corp., Raritan, N.J.) and L365209 (provided by Dr. D. Pettibone, Merck, West Point, N.Y.). The binding specificity was tested by competition with human chorionic gonadotropin (94% purity, Steris Laboratories, Phoenix, Ariz.), and thyrotropin releasing hormone (Thypinone, Abbott Laboratories, North Chicago, Ill.).

Protein assays were performed according to the method of Lowry et al.[20] with bovine serum albumin as standard, and deoxyribonucleic acid (DNA) assays were performed according to the method of Burton[21] with calf thymus DNA as standard.

Data analysis. Analysis of the data was performed with a computerized nonlinear iterative curve-fitting program, LIGAND, which calculates the parameters K_a (association constant), K_d (dissociation constant), K_i (dissociation constant of inhibitor), and B_{max} (maximum binding) (Biosoft, Elsevier Science Publishers, New York).

Statistical analysis. The significance of the cyclic variations was assessed by analysis of variance followed by Dunnett's test using log-transformed data, and Student's *t* test was used to compare differences between two groups; values of $p < 0.05$ were considered significant. Values are given as mean ± SE unless otherwise indicated; *n* indicates the number of cows or number of pools from human ovaries, respectively.

Results

Preliminary results with bovine ovarian tissues indicated that the binding of tritiated oxytocin and tritiated arginine vasopressin was proportional to the protein concentration up to 1.5 mg/ml; at 2 mg/ml nonspecific interactions began to occur. Saturation analysis with 0.4 and 0.8 mg/ml of protein from the same bovine ovarian

stromal membrane preparation resulted in identical K_d and B_{max} values, with SEs <10%. Specific binding reached equilibrium at 22° C in approximately 45 minutes and was stable until 90 minutes; at +4° C the equilibrium was reached in 2 hours. At 37° C the results were erratic and specific binding had declined to low levels at 90 minutes. The presence of a divalent cation was essential for binding; calcium was ineffective and manganese was more effective than magnesium. Nonspecific binding constituted from 50% to 80% of total binding, depending on the concentration of labeled ligand and the concentration of protein in the saturation assay. Thyrotropin releasing hormone or human chorionic gonadotropin, in concentrations up to 10^{-6} mol/L, did not compete for the binding of labeled oxytocin. The precision of the assay was determined by measuring the binding to aliquots of a similar membrane fraction prepared from bovine endometrium obtained on the day of estrus. Scatchard plots on the binding data obtained with these quality control samples in 15 assays yielded similar parameters as the original analysis on the same tissue.[19]

High-affinity, saturable binding sites for tritiated oxytocin were found in all ovarian tissues, including the human pooled ovarian tissues, bovine ovarian stroma, corpora lutea, and follicles (Fig. 1). Tritiated arginine vasopressing binding was found in all tissues examined except the bovine corpora lutea, which showed no binding. The affinities were similar for both peptides and for all tissues with no significant variations between tissues or days of cycle (Table I). Unlabeled oxytocin displaced the labeled ligand with a K_d of 0.5×10^{-8} mol/L, and unlabeled arginine vasopressin competed for tritiated oxytocin with high affinity, K_i 0.8×10^{-9} mol/L. Labeled arginine vasopressin was displaced by arginine vasopressin with a K_d of 1.4×10^{-8} and oxytocin competed with tritiated arginine vasopressin with a K_i of 0.8×10^{-9}, indicating a high degree of cross-reactivity at the binding sites. The selective oxytocin agonist isotocin competed for tritiated oxytocin with high affinity, whereas the selective antidiuretic agonist ddAVP competed with much lower affinity. The two selective oxytocin antagonists RWJ22165 and L365209 also competed for tritiated oxytocin binding sites with similar affinity as in myometrial and endometrial membranes.[18] Fig. 2 shows the logit-log transformed competition curves for the tested agonists and antagonists.

The sizes of the follicles and corpora lutea in the ovaries of the experimental cows are shown in Table II together with plasma progesterone levels at the time of slaughter and the luteal oxytocin content, which was measured in corpora lutea of other cows from the same herd slaughtered on the same days of cycle. The measurements were performed by radioimmunoassay with

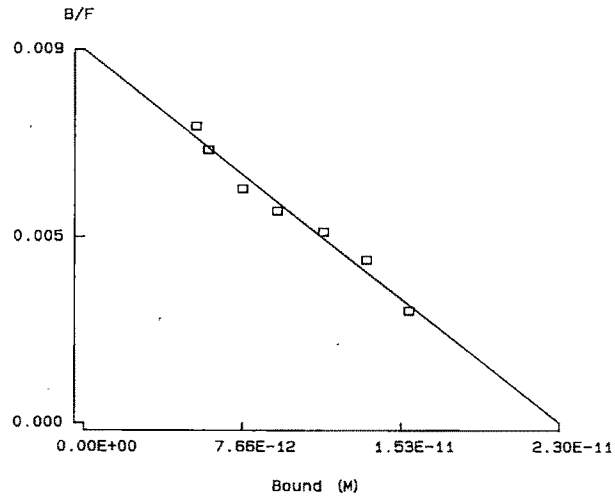

Fig. 1. Scatchard plot of data obtained in a saturation experiment with tritiated oxytocin binding to 400 μg of pooled bovine ovarian stromal membranes per tube. The ovaries were from days 17 and 21 of the estrous cycle.

Table I. Affinity constants of oxytocin and arginine vasopressin receptors in human ovarian tissue and bovine ovarian stroma, follicles, and corpora lutea obtained from saturation experiments

	Affinity constant (nmol/L)	
	Oxytocin	*Arginine vasopressin*
Human ovary, pooled	1.50 ± 0.4 (n = 5)	1.4 (n = 1)
Bovine ovarian stroma	1.53 ± 0.23 (n = 18)	2.10 ± 0.55 (n = 10)
Bovine follicles, pooled	0.92 ± 0.13 (n = 4)	0.45 (n = 1)
Bovine corpora lutea	2.55 ± 0.30 (n = 10)	No binding

Values are mean ± SE.

0.4 mol/L acetic acid extracts that were purified by absorption on Florisil columns with subsequent elution with 90% acetone water.

Human pooled ovarian tissues. The concentration of tritiated oxytocin binding sites per milligram of DNA rose progressively during the menstrual cycle from low levels in the proliferative phase (days 6 and 7), 71.7 ± 5 fmol/mg DNA, to 157 ± 60 mol/mg DNA in midcycle (days 14 to 18), and a peak of (652 mol/mg DNA) in the luteal phase (days 19 to 28). This value was more than three times the standard deviation above the mean for the proliferative phase and midcycle samples (Fig. 3). Expressed per milligram of protein, the variations during the cycle were similar; the concentration in the luteal phase was significantly higher than the combined mean for the proliferative phase and the midcycle val-

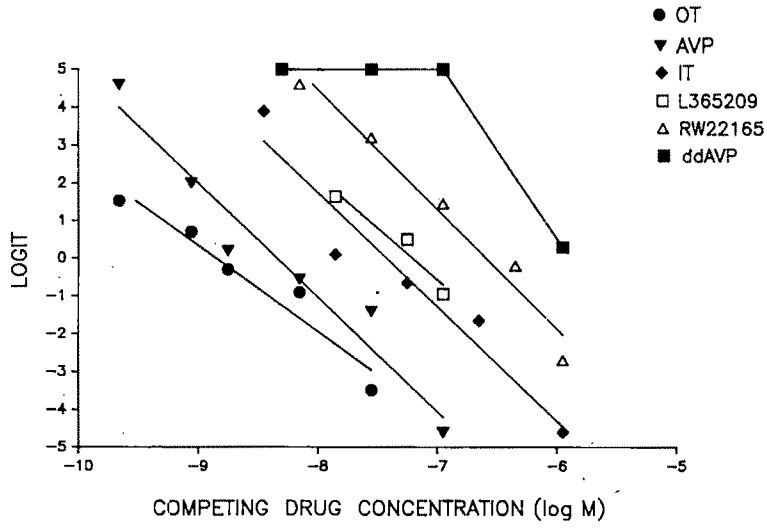

Fig. 2. Competition and displacement of tritiated oxytocin in membranes of pooled bovine ovarian stroma by various agonists *(closed symbols)* and antagonists *(open symbols)* plotted after logit-log transformation of the data. Specific binding in the absence of added unlabeled peptide was designated B_0. *IT*, Isotocin. L365209 and RWJ22165 are two oxytocin antagonists from Merck Co. and Ortho Corp., respectively.

Table II. Plasma progesterone levels, the size of the largest follicles, and weights of corpora lutea in the experimental cows, and luteal oxytocin content in cows of the same herd obtained on the same days of the cycle

Day	*Follicles* (mm)*	*Corpora lutea* (gm)*	*Plasma progesterone* (ng/ml)*	*Luteal oxytocin (pmol/gland)*
0	13.3 ± 3.1	1.3 ± 0.1	<0.2 ± 0	6
7	18.3 ± 2.4	3.7 ± 0.4	3.4 ± 0.2	1181
14	12.5 ± 3.6	4.6 ± 1.6	3.3 ± 0.4	2632
17	4.8 ± 1.3	3.6 ± 0.5	3.8 ± 1.9	227
19	—	3.0 ± 1.9	2.9 ± 1.2	195

Values are mean ± SE; n = 3 cows, except n = 2 for luteal oxytocin.

*Values are reproduced from Fuchs A-R, Behrens O, Helmer H, Liu C-H, Fields M, Barros C. Endocrinology 1990;127:629-39, courtesy of the Endocrine Society.

ues (results not shown). Tritiated arginine vasopressin binding was measured in only one pool because of a shortage of tissue. In that pool the femtomoles per milligram DNA concentration of the binding sites for tritiated arginine vasopressin was slightly higher than for tritiated oxytocin (Fig. 3).

Bovine ovarian stroma. The concentrations of oxytocin binding sites were lowest on day 14 (56 ± 22 fmol/mg DNA) and highest on day 21 (292 ± 64 fmol/mg DNA), but the variations were not significant by analysis of variance because of the considerable individual variations. When the values for the early and midluteal phase (days 7 and 14) and for the late luteal phase (days 17 to 21) were combined, the cyclic variations were statistically significant ($p < 0.05$); the combined late luteal phase values, 195 ± 41 fmol/mg DNA, were significantly higher than the combined early and midluteal phase values, 70 ± 15 fmol/mg DNA, ($p < 0.03$) (Fig. 4).

The concentration of arginine vasopressin binding sites was somewhat lower and showed a similar trend during the cycle as the oxytocin binding sites (54.1 ± 20 fmol/mg DNA on days 7 and 14 and 106 ± 48 fmol/mg DNA on days 17 to 21), but the differences were not statistically significant.

Expressed per milligram of protein, the cyclic variations were similar, and the values for tritiated oxytocin binding were significant by analysis of variance ($p < 0.05$, values not shown).

Bovine corpora lutea. Tritiated oxytocin binding sites were also found in the corpora lutea. The concentrations were very low or nondetectable in early and midluteal phase (days 7 and 14, 42 ± 35 fmol/mg DNA), but in late luteal phase (on days 17, 19, and 21), the concentrations of binding sites were significantly increased; the mean value for these days was 616 ± 93 fmol/mg DNA ($p < 0.005$) (Fig. 5). Maximal values were observed on day 19 (3740 ± 209 fmol/mg DNA). The old corpora lutea present on day 0 had concentrations varying from 263 to 602 fmol/mg DNA.

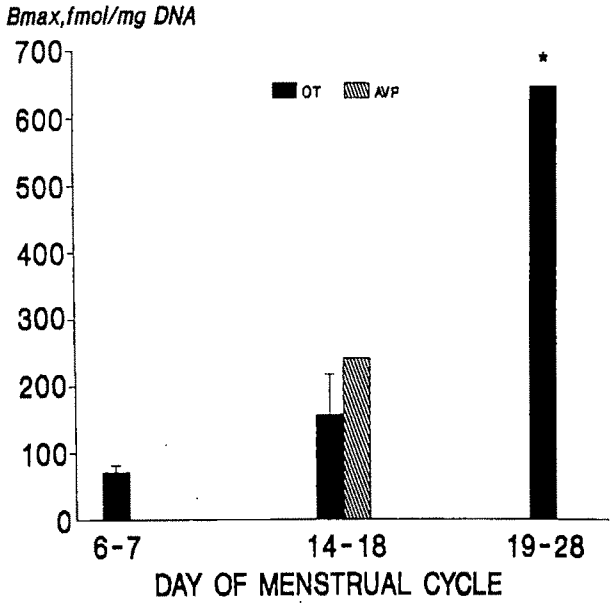

Fig. 3. Concentrations of specific binding sites for tritiated oxytocin and tritiated arginine vasopressin in human ovarian membrane preparations expressed in femtomoles per milligram of DNA. Tissues from two to three premenopausal patients were combined according to the phase of menstrual cycle to obtain sufficient tissue for saturation analysis. Two pools were analyzed for oxytocin binding on days 6 and 7 and 14 to 18, and one pool for oxytocin binding was analyzed on days 19 to 28 and for arginine vasopressin binding on days 14 to 18. *Asterisk* denotes significant difference from the combined means of the two other groups analyzed for oxytocin binding, $p < 0.01$.

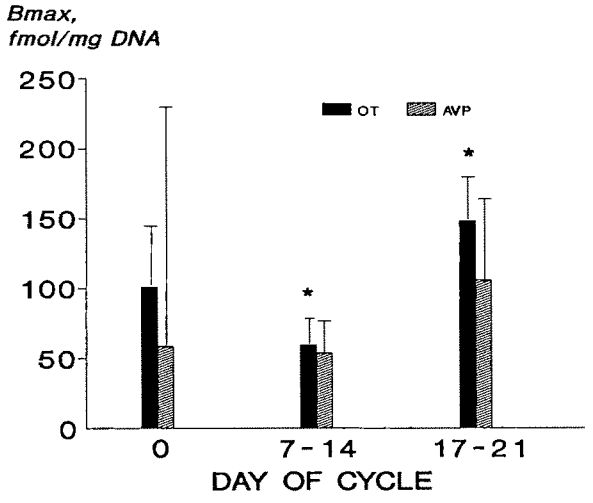

Fig. 4. Concentrations of specific binding sites for tritiated oxytocin and tritiated arginine vasopressin in bovine ovarian membrane preparations expressed in femtomoles per milligram of DNA. Large follicles and corpora lutea had been removed from the tissues. Values are log-normal mean ± SE. Results obtained for days 7 and 14 and for days 17 to 21 were combined. *Asterisks* denote groups that differed significantly.

No specific binding of tritiated arginine vasopressin was found on any day.

Bovine follicles. The largest follicle was dissected from each ovary and analyzed for tritiated oxytocin and tritiated arginine vasopressin binding sites. To obtain sufficient material for saturation analysis, all follicles from the same day of cycle were pooled. High-affinity, saturable binding sites for oxytocin were present on each day examined. The concentrations per milligram of DNA were higher than in the stroma. The concentration was highest on day 0 (475 fmol/mg DNA) and lowest on day 7 (76.2 fmol/mg DNA) and then increased progressively during the luteal phase to 308 fmol/mg DNA on day 17 (Fig. 6). Tritiated arginine vasopressin was bound with about equal affinity as tritiated oxytocin on day 0 (the only day examined for arginine vasopressin binding) but the concentration was about 50% lower than tritiated oxytocin binding, 292.5 fmol/mg DNA.

Comment

To our knowledge, this is the first demonstration of specific binding sites for the neurohypophysial peptides, oxytocin and arginine vasopressin, in bovine and human ovarian tissues. Corpora lutea of pregnant ewes were recently shown to bind tritiated oxytocin, whereas no binding was found in the corpora lutea of nonpregnant ewes.[22] In the nonpregnant cow, binding sites for tritiated oxytocin were present in the corpora lutea as well as in ovarian stroma and large follicles. The competition studies with selected agonists and antagonists with well-defined pharmacologic actions were compatible with the notion that the oxytocin binding sites represent biologic receptors. Whether the tritiated arginine vasopressin binding sites represent separate receptors cannot be stated on the basis of these results. The ovarian oxytocin binding sites resemble those in the uterus in their affinity to various analogs and in the cross-reactivity with arginine vasopressin.[18]

The results suggest that the two neuropeptides play a role in the regulation of ovarian function. Such a role has been postulated for oxytocin in sheep and cows on the basis of several physiologic observations, including the lengthening of estrus cycles in animals immunized against oxytocin,[23-25] and shortening of cycles in animals given injections of oxytocin at appropriate stages of the cycles.[11, 12] The effects of oxytocin on luteal function are best known in the ewe in which the action of oxytocin is thought to be indirect and mediated by $PGF_{2\alpha}$ released from the uterus under the influence of oxytocin.[3, 14, 15] In the cow, the influence of oxytocin on luteal function is still somewhat controversial. Lengthening or shortening of the cycle length has been reported, depending on the day of cycle oxytocin is administered.[11, 26] Oxytocin receptors are found in the cow endometrium in late luteal phase and around estrus,[19] on days when oxytocin has the ability to stimulate $PGF_{2\alpha}$

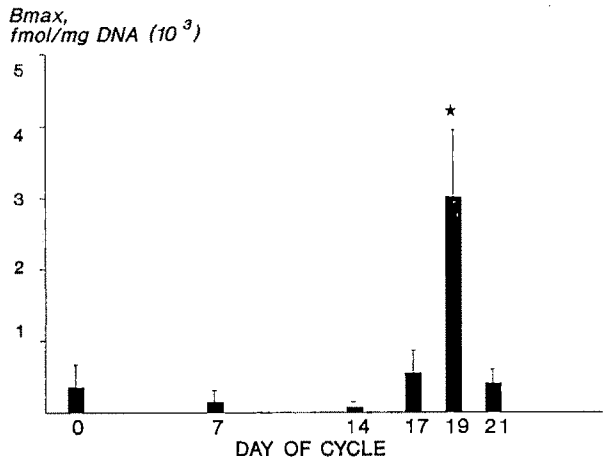

Fig. 5. Specific binding of tritiated oxytocin to membrane preparations from bovine corpora lutea expressed in femtomoles per milligram of DNA. Note that ordinate is in picomoles per milligram DNA (fmol × 10^3). *Asterisk* indicates significant differences from all other groups, $p < 0.005$ (analysis of variance). No specific tritiated arginine vasopressin binding was observed on any day of cycle.

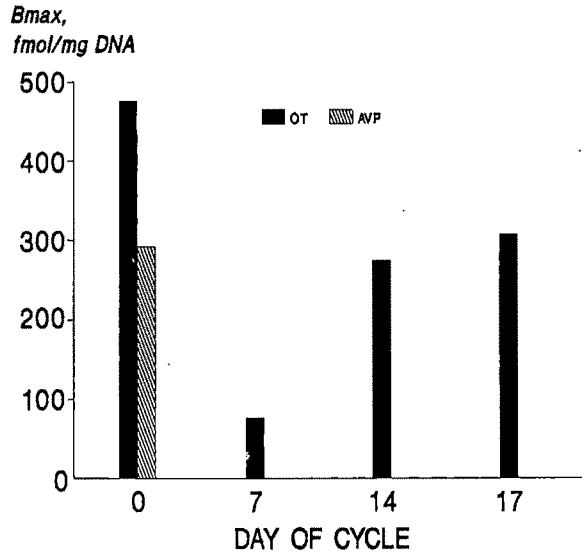

Fig. 6. Specific binding of tritiated oxytocin and tritiated arginine vasopressin to membrane preparation from large bovine follicles expressed in femtomoles per milligram of DNA. All follicles from cows killed on the same day of cycle were pooled to obtain sufficient material for saturation analysis. Tritiated arginine vasopressin binding was measured in only one pool, consisting of follicles from days 0 and 21 combined.

release from the endometrium in vitro[27] and increase uterine vein $PGF_{2\alpha}$ levels in vivo.[28] At least part of the oxytocin effect on luteal function in the bovine may therefore be mediated by uterine $PGF_{2\alpha}$ release as it is in sheep. However, our results suggest that oxytocin may also have direct effects on the ovary in general and corpus luteum in particular, since the rise in luteal oxytocin receptor concentrations was coincident with the beginning of the decline in plasma progesterone, reported earlier[19] and shown in Table II. The failure to show significant effects of oxytocin on luteal progesterone production in vitro may be a result of the fact that most investigators have used luteal tissue obtained on days 7 to 14, when oxytocin binding sites are at their nadir.

Bovine stromal and human ovarian oxytocin receptor concentrations also were increased when luteal regression began. The ability of oxytocin to effect the release of $PGF_{2\alpha}$ from the ovarian stroma has been demonstrated in rat ovaries.[29] Our findings therefore are compatible with a paracrine role for ovarian oxytocin in luteolysis in the bovine and possibly in the human. The synthesis of oxytocin in bovine,[8,9] ovine,[3] and porcine[4] ovaries and corpora lutea is firmly established, whereas the synthesis of oxytocin in primate ovaries is still controversial.[3,6] However, the recent demonstration of oxytocin production by human granulosa cells in culture is a strong indication of the ability of human ovaries to synthesize oxytocin de novo.[10] It is significant that arginine vasopressin binding sites also were present in human ovaries, since primate ovaries were recently found to secrete significantly more arginine vasopressin than oxytocin in the late luteal phase.[30]

The stromal oxytocin and arginine vasopressin receptors may also mediate the contractile effects of the neuropeptides on the ovary.[31,32] Myoepithelial cells have been identified in perifollicular tissue[33] and contractile proteins were identified in thecal cells [34] Although the localization of oxytocin and arginine vasopressin receptors within the ovary remains to be established, the smooth muscles like perifollicular cells located in the theca are likely sites for such receptors. It is also possible that arginine vasopressin receptors are located in ovarian vascular tissue and are involved in the regulation of ovarian blood flow.[35] It is not yet known whether the ovarian arginine vasopressin receptors are of the VP1 type present in vascular tissue or the uterine type present in endometrium and myometrium.[18,19]

The finding of oxytocin binding sites in follicles indicates that oxytocin may have actions other than the luteolytic and contractile effects in ovarian function. Oxytocin has been implicated in the process of ovulation in the rat,[28] acting perhaps on the outermost theca cells expressing muscle characteristics.[34]

In conclusion, human ovarian tissue and bovine ovine stroma, large follicles, and corpora lutea possess specific tritiated oxytocin binding sites. With the exception of bovine corpora lutea, tritiated arginine vasopressin binding sites were also found in ovarian tissues. In humans, the concentrations of tritiated arginine vasopressin binding sites were similar as tritiated oxytocin; in the bovine they were somewhat lower. The binding sites showed considerable cross-reactivity be-

tween the two hormones. The competiton for the specific binding of tritiated oxytocin by the two oxytocin antagonists suggests that the binding sites represent receptors. Their concentrations varied during the estrous cycle and were low in human proliferative phase and in early human and bovine luteal phase with a significant rise in late luteal phase in both species. These variations are compatible with the hypothesis that oxytocin has a paracrine role in the regulation of luteal function in both species. The binding sites in the stromal tissue and follicles may also mediate contractile responses to the two neuropeptides. The presence of high concentrations of binding sites in periovulatory follicles suggests that oxytocin and perhaps arginine vasopressin may play a physiologic role in follicular rupture.

Correlation of the testicular determinant factor sequence zinc finger Y with varying gonadal phenotypes in a series of 13 subjects with gonadal dysgenesis due to Y aneuploidy

Sandra P.T. Tho, MD,[a] Ali Behzadian, PhD,[a, b] J. Rogers Byrd, PhD,[c] and Paul G. McDonough, MD[a]

Augusta, Georgia

Deoxyribonucleic acid samples from a series of 13 subjects with 45,X/46,X,altered Y, and varying gonadal phenotypes (streak-streak, $n = 9$; streak-testis, $n = 2$; testis-testis, $n = 2$) were analyzed for the presence of the candidate testicular determinant factor sequence zinc finger Y.[1] The Y-specific probes Y97 mapped to Y centromere, pDP105 A,B mapped to Yp and distal Yq11, respectively, hybridized with the deoxyribonucleic acid from all the 13 study subjects. The same deoxyribonucleic acid samples were analyzed for the presence of the zinc finger Y sequence. Eleven of the 13 subjects were positive for the zinc finger Y sequence. Four zinc finger Y–positive subjects had unilateral ($n = 2$) or bilateral ($n = 2$) testicular differentiation. Among the nine subjects with bilateral streak gonads, seven showed the presence of this sequence. The lack of testicular differentiation in the presence of quantitatively normal or almost normal zinc finger Y bands could not be explained by mosaicism alone. Mutations not detectable by analysis with the method of Southern with pDP1007, may occur in the testicular determinant factor gene vitiating testicular development. (Am J Obstet Gynecol 1990;163:1968-75.)

Key words: Testicular determinant factor, zinc finger Y, zinc finger X, mixed gonadal dysgenesis, Turner syndrome

Chromosomal constitutions derived from Y aneuploidy cover a wide range of 45,X/46,XY mosaicisms with varieties of Y morphology including normal Y, nonfluorescent minutes, and large fluorescent dicentric fragments. The resultant phenotypes vary from classic Turner female with bilateral rudimentary streaks to normal male phenotype with bilateral atrophic scrotal testes through degrees of sexual ambiguity with unilateral abdominal streak and contralateral abdominal or scrotal testis.[2, 3] In rare subjects with typical Turner phenotypes, unilateral streak and contralateral testis, the expected 45,X cell line may have been lost with time. These unique subjects remain nonmosaic 46,XY on the basis of chromosomal analysis of multiple tissues.[4, 5] Conversely, the 46,XYcell line may disappear and the subject remains nonmosaic 45,X, yet carrying a unilateral streak gonad and a contralateral testis.[6] There does not seem to be a consistent karyotypical gonadotypical correlation because the same degrees of mosaicism and similar structural alterations of the Y chromosomal fragments may be associated with either a typical Turner female harboring bilateral streaks or a normal male with bilateral scrotal testes or a sexually ambiguous individual with classic mixed gonadal dysgenesis. Recently, by chromosome walking, Page and coworkers[1] isolated a 140 kilobase (kb) region of Yp, which initially was thought to be the sole testicular determinant factor gene. A deoxyribonucleic acid (DNA) probe, pDP1007, isolated from an exon of the coding region of this gene yields a Y-specific band mapped to distal Yp and a smaller molecular weight X-specific band mapped to Xp22.1-p22.2. Sequence analysis indicated that the Y-specific sequence encodes a DNA binding protein with zinc finger domains. This sequence has been called zinc finger Y. The homologous sequence on X has been referred to as zinc finger X.[7] Furthermore, zinc finger Y has proved to be conserved in most mammals. Despite much controversy,[8-11] the zinc finger Y sequence by its conserved nature and its regulatory function appears to play an important role in testicular differentiation.

The frequency of Y chromosomal rearrangements and the lack of karyotype-gonadotype correlation have prompted us to assess the presence or absence of the zinc finger Y sequence in these structurally compromised Y-derived fragments. Comparison of molecular findings with gonadal phenotypes in a series of 13 subjects with 45,X/46,X,altered Y is the primary objective

of this report. The study also provides a molecular deletion mapping of a wide variety of structurally rearranged Y chromosomes in gonadal dysgenesis due to Y aneuploidy.

Material and methods

Thirteen of the 22 subjects with gonadal dysgenesis and 45,X/46,X,mar karyotype were ascertained to carry Y DNA with two Y-specific probes: Y97 mapped to Y centromere, pDP105 mapped to Yp and Yq11. The remaining nine subjects who were negative for these two probes were presumed to harbor X-derived markers and were not included in the study. The Y-specific probe 4B-2 mapped to Yq11 was used for delineation of the break points of these Y fragments. The 13 subjects were also analyzed for the candidate testicular determinant factor probe pDP1007 and attempts were made to compare testicular differentiation with the presence of the zinc finger Y sequence.

DNA probes. Fig. 1 illustrates the schematic map of the Y chromosome with the seven deletion intervals of Vergnaud et al.[12] and representation of the four Y DNA probes used in this study. The cosmid Y97 (DYZ3) isolated from a cosmid Y library contains one copy of the 5.5 kb *Eco*RI fragment of the Y centromere–specific alphoid DNA. Human genomic DNA restricted with *Eco*RI and hybridized to the Y97 probe shows a 5.5 kb Y-specific band.[13] The probe pDP105 (DYZ4) isolated by Page is a 5.5 kb *Hin*dIII genomic fragment inserted into the *Hin*dIII site of pUC13. This probe hybridizes with *Taq* I digested human DNA, yielding a 2.5 kb Y-specific band (pDP105/A), marker for interval 3 on Yp, and a 5.2 kb Y-specific band (pDP105/B), marker for interval 6 on Yq11.[14] The probe 4B-2 (DYS15) is a recombinant phage construct containing a 3.3 kb single copy *Eco*RI fragment that maps to Yq11. This 3.3 kb fragment resulting from *Eco*RI digest of the recombinant phage was subcloned into the *Eco*RI site of plasmid pBR322.[15] Human DNA restricted with *Eco*RI and hybridized to the 4B-2 probe yields the Y-specific 3.3 kb band, marker for interval 5 on Yq11. The probe pDP1007 (zinc finger Y, zinc finger X) is a 1.3 kb *Hin*dIII genomic fragment cloned into the *Hin*dIII site of pUC13. It derives from interval 1A2 of the human Y chromosome. Genomic human DNA digested with *Eco*RI and hybridized with pDP1007 exhibits a Y-specific 3.5 kb band and an X-specific 1.8 kb band, mapped to Xp22.1-p22.2.[1] The cosmid Y97 and the plasmids pDP105, 4B-2, and pDP1007 were propagated, amplified, and isolated by conventional methods.[16] The corresponding inserts were released from their vectors by restriction digest with the appropriate enzymes and purified through electrophoresis, phenol extraction, and ethanol precipitation. Before hybridization, the probe pDP1007 was radiolabeled by nick translation[17] and the other three probes by oligonucleotide random priming[18] to specific activity of 1 to 5×10^8 cpm/μg DNA.

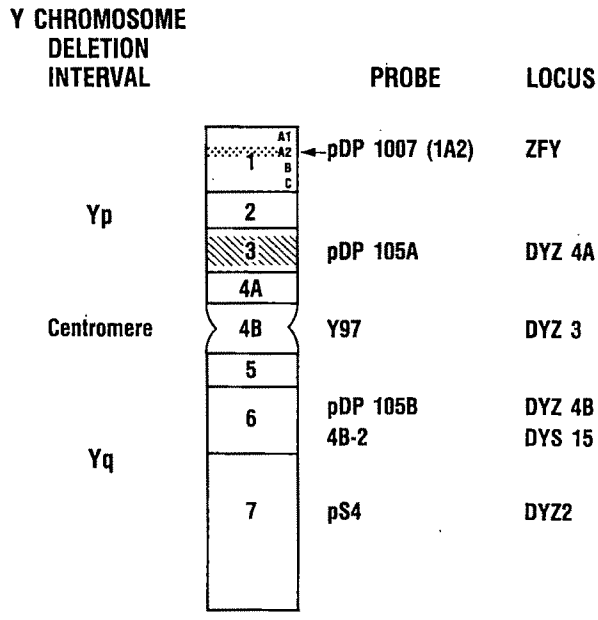

Fig. 1. Schematic map of Y chromosome with representation of seven deletion intervals of Vergnaud[12] and four Y-specific probes Y97, pDP105, 4B-2, and pDP1007. *DYZ2:* D = DNA, Y = Y chromosome, Z = repetitive copy DNA, 2,3,4 indicate published order of specific cloned DNA sequence; *DYS15:* D = DNA, Y = Y chromosome, S = single copy, 15 indicates published order of cloned DNA sequence; *ZFY:* ZF = Zinc finger protein encoding sequence, Y = on Y chromosome.

Genomic DNA analysis. Human genomic DNA was extracted from peripheral leukocytes from normal control 46,XY men, 46,XX women, and from the 13 study subjects according to standard techniques. Aliquots of DNA were digested with the enzymes *Eco*RI for probes Y97, 4B-2, and pDP1007 and *Taq* I for the probe pDP105, and electrophoresed in 0.8% agarose gels. DNA was transferred to Gene Screen Plus filters (New England Nucleic Research Products, Boston) by the technique of Southern[19] and baked for 2 hours at 80° C. The blots were hybridized for 48 hours at 42° C with formamide to the ^{32}P-labeled probe pDP1007 and at 65° C to ^{32}P-labeled probes Y97, pDP105, and 4B-2. The blot hybridized with pDP1007 was washed at 55° C with decreasing concentrations of sodium chloride-sodium citrate (2 × sodium chloride-sodium citrate to 0.2 × sodium chloride-sodium citrate) and 1% sodium dodecyl sulfate. The blots hybridized with the other three probes were washed at high stringency conditions at 65° C with decreasing concentrations of sodium chloride-sodium citrate (2 × sodium chloride-sodium citrate to 0.2 × sodium chloride-sodium ci-

trate) and 1% sodium dodecyl sulfate. Autoradiographs were obtained by exposing the membranes with intensifying screens at −80° C from 1 to 3 days to Kodak XAR-5 film (Eastman Kodak Company, Rochester, N. Y.).

Specific experiments

Experiment I. Dilutional gel for probe pDP105. Decreasing amounts of normal 46,XY male DNA (5 to 0.025 μg) were mixed with normal 46,XX female DNA, digested with *Taq* I enzyme, and hybridized to the ^{32}P-labeled pDP105 probe at 65° C for 48 hours (5 μg/lane).

Experiment II. Dilutional gel for probe pDP1007. Decreasing amounts of normal 46,XY male DNA (5 to 0.025 μg) were mixed with normal 46,XX female DNA, digested with *Eco*RI enzyme, and hybridized to the ^{32}P-labeled pDP1007 probe at 42° C with formamide for 48 hours (5 μg/lane).

*Experiment III. Eco*RI *digest and pDP1007 probing of DNA from the 13 study subjects.* The clinical, cytogenetic, and molecular data are tabulated in Table I.

Clinical data. The clinical phenotype of the 13 subjects ranges from phenotypic male with bilateral scrotal testes (No. 13) to classic Turner phenotype with bilateral streak gonads (n = 9) and sexually ambiguous individuals (No. 2, streak-scrotal testis; No. 3, streak-abdominal testis; No. 6, bilateral abdominal testes). The three latter subjects, each with a vagina and a uterus on vaginoscopy and urethroscopy, have been reared as females and underwent clitoral resection and bilateral gonadectomy. Gonadal tumor occurred in four of the 13 subjects. In 3 subjects, a gonadoblastoma developed in one of the streaks (No. 7, No. 9, and No. 11) and the remaining one had a unilateral dysgerminoma (No. 8).

Cytogenetic studies. Chromosomal analysis was per-

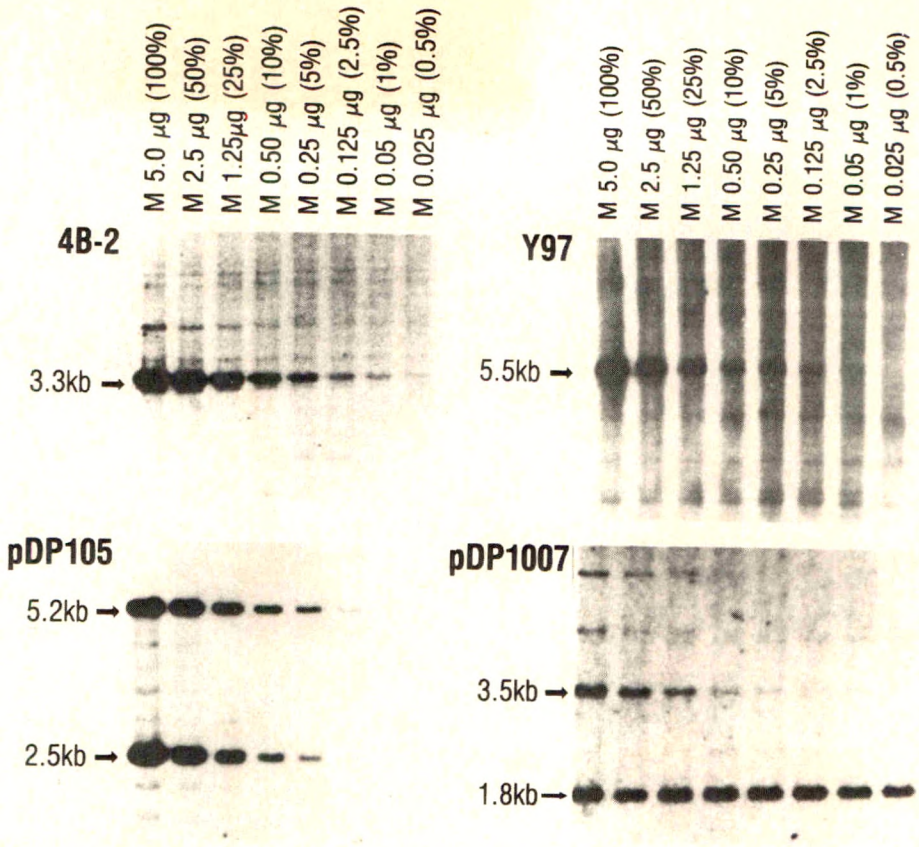

Fig. 2. Composite of four dilutional gels for probes 4B-2, Y97, pDP105, and pDP1007. All four dilution experiments were conducted in same fashion. Each lane contained 5 μg of DNA digested by appropriate enzymes and the blots of these four dilutional gels were hybridized separately to the four probes. *First lane on left* contained only male DNA (5.0 μg, or 100% male DNA). *Next lane* contained 2.5 μg male DNA (2.5 μg or 50% male DNA). Proportion of male DNA *(M)* gradually decreases to 0.5%. Y-specific 3.3 kb band with 4B-2 is seen at levels as low as 0.025 μg or 0.5% male DNA; 5.5 kb band with Y97 at 0.050 μg or 1% male DNA; 5.2 kb and 2.5 kb bands with pDP105 at 0.125 μg or 2.5% male DNA and 3.5 kb band with zinc finger Y at 0.250 μg or 5% male DNA.

formed on peripheral leukocytes in all subjects. Because cytogenetic studies on gonadal and nongonadal tissues are not available in some patients and because there are no good correlations between the numeric prevalence of the 46,XY cell line and testis formation,[2] the current investigation is limited to peripheral blood cells. A minimum of 50 cells was counted and five cells were karyotyped in each study sample. G-, Q-, and C-banding was carried out in all 13 cases. The altered sex chromosome was cytogenetically identified as Y-derived only in patient No. 3 who carries a large fluorescent isodicentric Y with undetermined break point on Yp. In patient No. 12, the sex chromosome was presumed to be Y-derived on the basis of the presence of a bright fluorescent band in the middle of an enlarged chromosome long arm. All the remaining cytologically altered chromosomal fragments were unidentifiable by conventional cytogenetic techniques.

DNA analysis of the study subjects. Aliquots of 10 μg of DNA from the 13 subjects with gonadal dysgenesis due to Y aneuploidy were analyzed with the four probes Y97, pDP105, 4B-2, and pDP1007.

Results

Experiment I. In dilution studies, the probe pDP105, a marker of interval 3 on Yp and of interval 6 on Yq11, may detect 125 ng of male DNA in mixture with 4.875 μg of female DNA (2.5%) (Fig. 2). We previously showed that the Y centromere–specific probe Y97 may detect 50 ng of male DNA in mixture with 4.950 μg female DNA (1%) and that the probe 4B-2, a marker for Yq11, may detect 25 ng of male DNA in mixture with 4.975 μg of female DNA (0.5%) (Fig. 2).

Experiment II. In dilution studies the probe pDP1007 mapped to distal Yp may detect 250 ng of male DNA in mixture with 4.750 μg of female DNA (5%) (Fig. 2).

Experiment III. (1) Southern analysis clearly showed the Y centromeric 5.5 kb *Eco*RI band with the Y centromere–specific probe Y97 in all 13 subjects. The

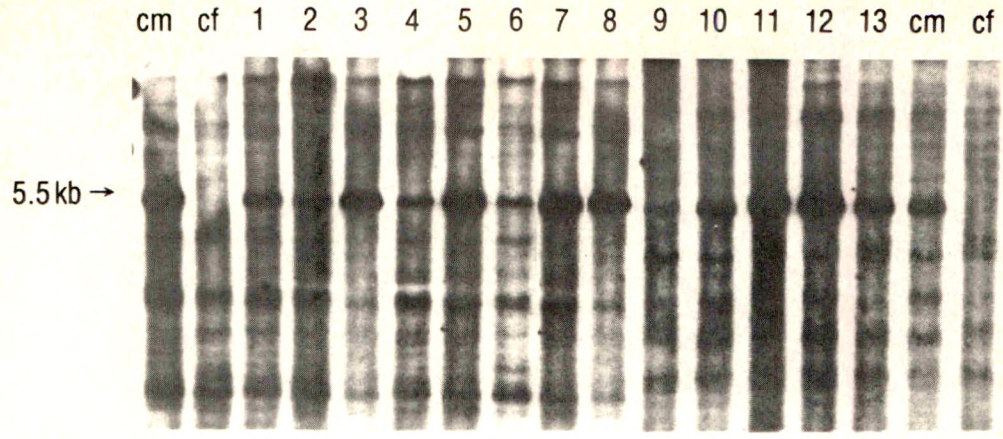

Fig. 3. Autoradiograph of *Eco*RI digest and Y97 probing of 13 study subjects (Nos. 1 to13). Centromeric Y-specific 5.5 kb *Eco*RI band is evident in control males *(cm)* and in all 13 subjects. It is absent in control females *(cf)*.

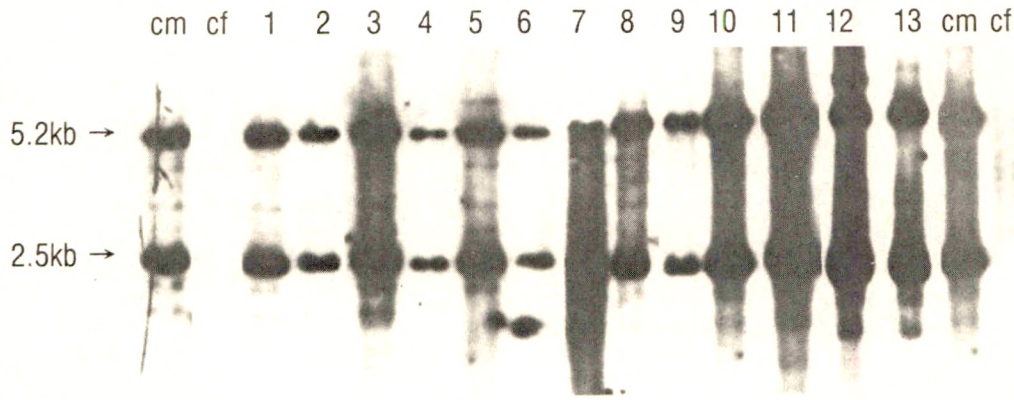

Fig. 4. Autoradiograph of *Taq* I digest and pDP105A/B probing of 13 study subjects. Y-specific 2.5 kb *Taq* I band, marker of interval 3 of Yp (pDP105/A), and 5.2 kb *Taq* I band, marker of interval 6 of Yq11 (pDP105/B), are seen in control males *(cm)* and in all 13 subjects. They are absent in control females *(cf)*.

intensity of the bands is in gross agreement with the importance of the mosaic Y cell lines (Fig. 3); (2) the Y-specific 2.5 kb *Taq* I hybridization band with the pDP105/A sequence, marker of Yp at interval 3, and the 5.2 kb *Taq* I hybridization band with the pDP105/B sequence, marker of Yq11 at interval 6, are also evident in all 13 subjects. The intensity of these two bands is mostly consistent with the percentage of the mosaic Y-bearing cell lines (Fig. 4); (3) the Y-specific 3.3 kb *Eco*RI hybridization band with the 4B-2 probe, marker of Yq11, is present only in six of the 13 study subjects. The break point in four (No. 1, No. 4, No. 5, and No. 10) of these six subjects is probably at the Yq11-Yq12 junction. In the fifth subject (No. 3), Yq is intact and the break point would be in terminal Yp. Fusion of the two Y chromosomes at their break points results in the formation of a isodicentric Y. In the sixth subject (No. 12), the break point is within Yq12 and fusion of the two Y chromosomes at their break points results in an unusual isodicentric Y chromosome with a fluorescent band in the middle of an enlarged derivative Yq. In the seven 4B-2–negative subjects the break point would be at the junction of the pDP105/B and the 4B-2 sequences within distal Yq11 (Fig. 5); (4) the Y-specific 3.5 kb *Eco*RI hybridization band with the pDP1007 probe is present in 11 of the 13 study subjects. The intensity of the band is compatible with the proportion of Y cells in nine of the 11 zinc finger Y–positive subjects. In the tenth subject (No. 1), the band is darker than expected and in the eleventh subject (No. 10), the band is lighter than expected (Fig. 6).

The two zinc finger Y–negative subjects seem to have a more extensive deletion involving both Y long and short arms leading to the formation of two minuscule fragments that did not stain on C-banding and were

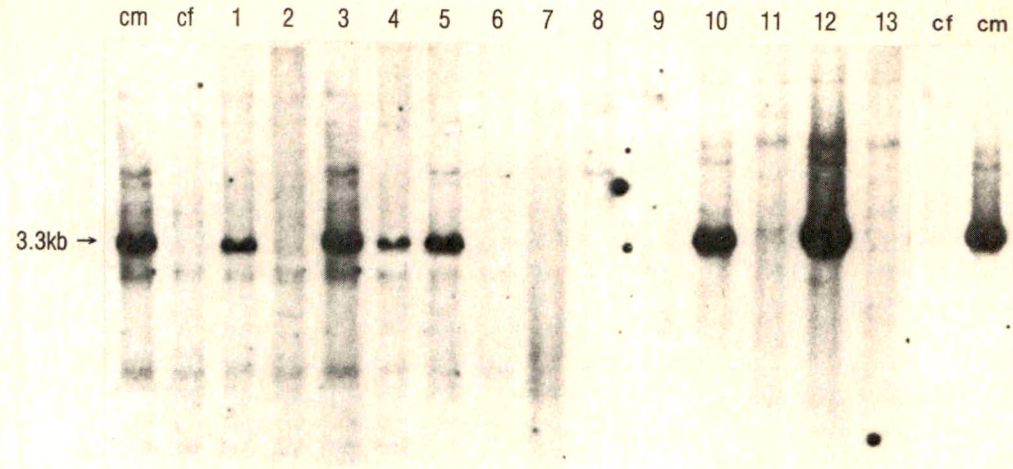

Fig. 5. Autoradiograph of *Eco*RI digest and 4B-2 probing of 13 study subjects. Y-specific 3.3 kb *Eco*RI band, marker of Yq11, is shown in control males *(cm)* and in six study subjects (Nos. 1, 3, 4, 5, 10, and 12). It is absent in control females *(cf)* and in remaining seven study subjects.

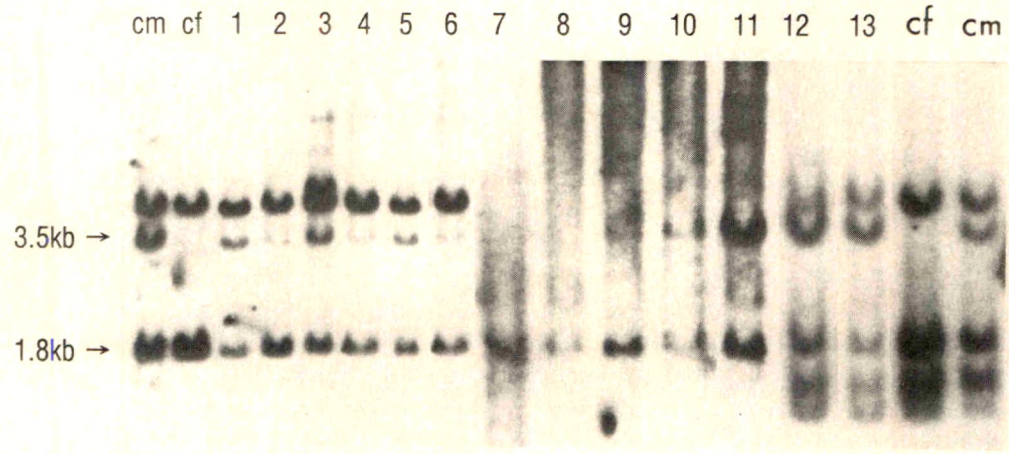

Fig. 6. Autoradiograph of *Eco*RI digest and pDP1007 probing of 13 study subjects. Y-specific 3.5 kb *Eco*RI (zinc finger Y) band is present in control males *(cm)* and 11 of 13 subjects with Y aneuploidy. It is absent in control females *(cf)* and in two subjects (Nos. 7 and 8) whose Y chromosomes are barely perceptible fragments. Phenotypically normal male (No. 13) and two typical Turner females (Nos. 11 and 12) have normal zinc finger Y bands.

thought to be "acentric" before molecular studies. Both subjects harbor bilateral streak gonads.

Among the 11 zinc finger Y–positive subjects, 7 were found to have only bilateral streak gonads; four had testicular differentiation ranging from bilateral scrotal testes with normal male phenotype (No. 13) to bilateral abdominal testes (No. 6) or unilateral testis (Nos. 2 and 3). The zinc finger Y band is normal in the subject with male phenotype (No. 13). It is almost normal in the subject with dic(Y) and unilateral abdominal testis (No. 3). However, the other two subjects (No. 2) with unilateral scrotal testis and (No. 6) with bilateral abdominal testes had a much reduced zinc finger Y band. Conversely among the seven zinc finger Y–positive subjects who harbor bilateral streaks, two had normal zinc finger Y bands (Nos 11 and 12), two a moderately reduced band (Nos. 1 and 5), and three had a significantly reduced zinc finger Y band (Nos. 4, 9, and 10).

Comment

Two thirds of XX males harbor on their paternal X, DNA material from the paternal Y chromosome short arm including the critical 140 kb region that is the candidate testicular determinant factor gene. Conversely, a few XY females with molecular deletions of Yp have been reported with Turner phenotype and

bilateral streak gonads.[20-22] The most conserved exon of the putative testicular determinant factor gene, represented by the zinc finger Y sequence (probe pDP1007), encodes a transcription protein with zinc finger domains.[1] The mechanism of testicular determination and the biochemical function of zinc finger Y are still unclear because it is unknown what these zinc fingers regulate. Cases of absence of Y sequences in 45,X mixed gonadal dysgenesis[6] and integrity of Y DNA in a nonmosaic 46,XY subject with unilateral streak and contralateral testis[5] would suggest that mosaicism alone cannot account for a complete or partial failure of testicular differentiation in several subjects with Y aneuploidy. One might argue that the gonadal phenotype depends on the relative prevalence of 46,XY cells versus 45,X cells in the gonad during embryonic development. One might also argue that the gonadal phenotype in typical mixed gonadal dysgenesis may theoretically reflect the relative prevalence of the 45,X cell line in the adult streak gonad versus the prevalence of the 46,XY cell line in the adult testis. Neither of these theories is supported by data and both would exclude Y chromosomal or Y gene mutations as the primary cause of abnormal gonadal differentiation. The large number of cytologically abnormal Y chromosomes in these subjects supports Y molecular rearrangements and makes one suspect Y gene mutations.

This is the first report of which we are aware that assesses the molecular integrity of Y DNA in a large series of subjects with gonadal dysgenesis with differing segments of the Y chromosome conserved and correlates the conserved segments with the presence of zinc finger Y. All 13 subjects harbor the Y centromere and Yp up to interval 3 (pDP105/A) and Yq down to distal interval 6 (pDP105/B) (Table I; Figs. 1, 3, and 4). Only two subjects lost the zinc finger Y sequence on distal Yp (Nos. 7, and 8) and both had only bilateral streak gonads (Table I, Fig. 6). No subject was identified as having testes and lacking the zinc finger Y sequence. All subjects (n = 4; Nos. 2, 3, 6, and 13) with unilateral or bilateral testes are positive for this sequence (Table I, Fig. 6). The phenotypically normal male with bilateral scrotal testes does have a normal zinc finger Y band (No. 13), whereas one of the three sexually ambiguous subjects shows almost a normal zinc finger Y band (No. 3). However, the remaining two sexually ambiguous subjects exhibit reduced zinc finger Y bands (Nos. 2 and 6). Conversely, the seven subjects with complete failure of testicular differentiation and bilateral streak gonads (Nos. 1, 4, 5, 9, 10, 11, and 12) are also positive for the zinc finger Y sequence. It is intriguing that four of these subjects shows moderate size (Nos. 1 and 5) to normal size (Nos. 11 and 12) zinc finger Y bands and they still failed to have any testicular development. For the remaining three (Nos. 4, 9, and 10) the zinc finger Y bands are as reduced as for the subject with unilateral scrotal testis (No. 2) and the subject with bilateral abdominal testes (No. 6).

The lack of testicular development in subjects who carry the sequence suspected to be testicular determinant factor may be attributed to quantitative or qualitative factors. The quantitative factor involves a critical threshold of genetically normal Y-bearing cells during early embryogenesis. The qualitative factor is related to qualitative changes in structural or regulatory genes involved in the testicular differentiation pathway. It is almost impossible to assess the quantitative factor. This report, which shows the complete lack of testicular development despite the presence of apparently adequate amounts of zinc finger Y sequence, and, conversely, testis development despite significantly reduced zinc finger Y, suggests that mosaicism per se may not completely account for lack of testicular development. This assumption is further supported by sporadic case reports of nonmosaic 46,XY mixed gonadal dysgenesis with all Y DNA sequences preserved.[5] The lack of testicular development in this situation should raise the possibility that point mutations, frame shift mutations, not detectable by Southern analysis with pDP1007, may occur in the structural and regulatory portions of the testicular determinant factor gene, vitiating testicular development.

Palmer et al.,[11] in a continuing evaluation of the Yp region, identified sequences distal to but not including the testicular determinant factor region of Page that are exclusively present in a small subset of zinc finger Y–negative XX males. Four of these 14 zinc finger Y–negative XX males were found positive for three Y-specific pseudoautosomal boundary probes. However, none of the four patients had the classic phenotype of XX males. Palmer et al. reaffirm the current controversy between the zinc finger Y locus by Page and the pseudoautosomal boundary region as the potential testicular determinant factor candidate. In the female withY;22 translocation and bilateral streak gonads used by Page for the isolation of testicular determinant factor, the 140 kb testicular determinant factor region is absent but the pseudoautosomal boundary region locus preserved. Palmer et al. excluded position polymorphism only on the basis of a population of 150 controls. This controversy only points out the need for further studies of both the candidate testicular determinant factor locus of Page and the pseudoautosomal boundary region locus of Palmer. Most importantly the zinc finger Y sequence of Page encodes a protein with zinc fingers that have DNA binding properties. The pseudoautosomal boundary region described by Palmer et al. is not known to encode protein products.

This report also provides the deletion map of a wide variety of rearranged Y chromosomes seen in the Y

aneuploidy syndrome. It is interesting that most break points are limited to distal Yq11 or to Yq12 and that the zinc finger Y locus is spared even in Yp deletions (Nos. 3 and 9). The most extensive deletions as in subjects Nos. 7 and 8 are associated with gonadal neoplasia. The comparison between molecular genotype and gonadotype in these subjects with a wide variety of altered Y chromosomes provides an important body of primary data for further investigations of the role of zinc finger Y and of the pseudoautosomal boundary region in testicular determination. Analysis of the DNAs of these subjects with different gonadal phenotypes with the use of different exons from both the putative testicular determinant factor region of Page and the pseudoautosomal boundary region of Palmer should be the subsequent steps to clarify the role of Y sequences in initiating human testicular differentiation.

We gratefully acknowledge Dr. David Page for providing the probes pDP105 and pDP1007, Dr. Robert Erickson for providing the probe Y97, and Dr. Kirby Smith for providing the probe 4B-2.

Isolation and characterization of the gene from a human genome encoding 17β-estradiol dehydrogenase: A comparison of Jar and BeWo choriocarcinoma cell lines

Cecil A. Long, MD,[a] Gregory S. Bauer,[a, c] Mark E. Lowe, MD, PhD,[b] Arnold W. Strauss, MD,[b, c] and Michael J. Gast, MD, PhD[a]

St. Louis, Missouri

17-β-Estradiol dehydrogenase is required for the enzymatic interconversion of estradiol and its weaker related sex steroid, estrone. We isolated and sequenced a complementary deoxyribonucleic acid clone for 17β-estradiol dehydrogenase from the BeWo choriocarcinoma cell line. Comparison of the BeWo complementary deoxyribonucleic acid sequence to a previously derived placental complementary deoxyribonucleic acid sequence yields >98% homology. We also isolated the gene for 17β-estradiol dehydrogenase from the Jar human choriocarcinoma cell line and elucidated its primary nucleic acid structure. Significant differences in the Jar-deduced complementary deoxyribonucleic acid sequence clearly differentiate it from both the human placental and BeWo forms of 17β-estradiol dehydrogenase, indicating the existence of two genes for 17β-estradiol dehydrogenase in the human genome. Evaluation of 17β-estradiol dehydrogenase gene expression in BeWo and Jar cells was compared with expression in luteinized granulosa cells. Messenger ribonucleic acid for human placental 17β-estradiol dehydrogenase was identified in all three cell types as a 1.3 kilobase band on Northern blot analysis. A second messenger ribonucleic acid species measuring 2.1 kilobase was abundantly present in the granulosa cells. Whether these two species of messenger ribonucleic acid are involved in the regulation of the estradiol dehydrogenase genes is yet to be determined. (Am J Obstet Gynecol 1990;163:1976-81.)

Key words: 17β-Estradiol dehydrogenase, choriocarcinoma, estrogen metabolism

17β-Estradiol dehydrogenase (synonym, 17-ketosteroid oxidoreductase) occupies a pivotal position in the enzymatic cascade catalyzing the terminal step of estrogen biosynthesis. The enzyme is necessary for the reversible interconversion of estradiol and its weaker related steroid, estrone. It has also been suggested that the same enzyme may play a role in the interconversion of androstenedione and testosterone. 17β-Estradiol dehydrogenase may be involved in female well being in many widely varied areas including maintenance of bone and tissue integrity in menopause, control of the initiation of labor, uterine quiescence, and the ovarian-hypothalamic feedback system. In addition, 17β-estradiol dehydrogenase deficiency, although rare, can lead to male pseudohermaphroditism.[1]

The amino acid composition and biophysical properties of 17β-estradiol dehydrogenase have been elucidated through gel chromatography and active site topographic study with radioalkylated steroids and cofactors.[2-4] The enzyme exists as a 68,000-dalton dimer and uses pyridine nucleotides as cofactors. Activity of 17β-estradiol dehydrogenase has been shown in a wide variety of steroidogenic and nonsteroidogenic tissues; however, the most focused investigations have been with human placental 17β-estradiol dehydrogenase.

Specific activities of 17β-estradiol dehydrogenase from placenta and established gestational choriocarcinoma cell lines have been measured.[5] Although variable levels of 17β-estradiol dehydrogenase activity can be obtained in placental tissue, JEG-3, and BeWo cells, no 17β-estradiol dehydrogenase activity is noted in Jar cells. In addition, Western blot analysis has failed to show the presence of immunodetectable placental 17β-estradiol dehydrogenase-type enzyme in Jar cells.[5] To our knowledge, no mechanism has been established to explain the enzyme deficiency in the Jar cell line.

Three differing human placental 17β-estradiol dehydrogenase complementary deoxyribonucleic acid (cDNA) clones, including our own,[6-8] have previously

been isolated and sequenced. Sequence comparison of the clones reveals >95% homology. In situ hybridization studies[7] suggest that the human gene encoding 17β-estradiol dehydrogenase is located on the long arm of chromosome 17. The present investigation was undertaken to isolate and characterize the gene encoding 17β-estradiol dehydrogenase from a human genomic library, as well as define and compare gene expression in tumor cell lines with that of normal cells.

Methods

Isolation and DNA sequence analysis of BeWo cDNA and Jar genomic DNA. A cDNA library derived from messenger ribonucleic acid (mRNA) isolated from BeWo cells was constructed in the bacteriophage vector λgt10. Initial screening of the library was performed with a phosphorus 32–labeled 1100 base pair cDNA fragment from a human placental 17β-estradiol dehydrogenase clone, which we previously isolated and characterized.[8] 17β-Estradiol dehydrogenase–bearing plaques were purified by repeated screening with a modified version of the technique of Wahl and Berger.[9] Several of the clones were then amplified, their phage DNA was subjected to restriction endonuclease digestion, and they were subcloned into the sequencing vector pGEM4Z (Promega, Inc., Madison, Wis.). The largest of these clones measured 1.4 kilobases (kb) and was used for sequencing and subsequent library screening procedures. Sequencing was performed by a modification of the dideoxy chain termination method of Sanger with T7 DNA polymerase (Pharmacia, Piscataway, N.J.). Universal and specific synthetic oligonucleotides were used as sequencing primers.

A human genomic DNA library derived from the Jar choriocarcinoma cell line was provided by Dr. Irving Boime (Washington University, St. Louis). The library was screened with an 1100 base pair BeWo choriocarcinoma cDNA probe derived by Bam H1 digestion of the 1.4 kb clone. Once again, labeled plaques were lifted and further purified by rescreening at progressively lower plaque densities until several homogenous positive phage populations were identified. Three clones were then amplified and their phage DNA subjected to multiple restriction enzyme digestion. Southern blot analysis with the complete BeWo cDNA as well as fragments from both its 5′ and 3′ ends suggested that the entire Jar 17β-estradiol dehydrogenase gene was present in a single 6.0 kb fragment restricted by the enzyme *Kpn* I. This *Kpn* fragment and a smaller 1.7 kb *Sac* fragment that also hybridized to the 5′ end of the BeWo clone were then subcloned and sequenced by dideoxy chain termination.

RNA isolation and Northern blot analysis. Two different human choriocarcinoma cell lines, BeWo and Jar, were obtained from the American Type Culture Collection. Both of these gestational choriocarcinoma lines were developed from metastatic choriocarcinoma after a normal term birth.[10, 11] The cells were cultured in Dulbecco's modified Eagle's medium enriched with 15% fetal calf serum. Luteinized granulosa cells were obtained from follicle aspirations of patients undergoing ovarian hyperstimulation for in vitro fertilization.

Total RNA was isolated from BeWo, Jar, and granulosa cells by single-step guanidinium thiocyanate-chloroform extraction.[12] Fifteen micrograms of total RNA from each sample was separated on a 1.5% agarose–0.66 molar formaldehyde denaturing gel and transferred to a Gene Screen membrane (Biotechnology Systems NEN Research Products, Boston, Mass.). Overnight hybridization at 42° C was performed with a ^{32}P-labeled 1100 base pair BeWo fragment. The blot was then taken through a series of washes of increasing stringency with the final wash in 0.1X standard saline citrate/0.1% sodium dodecylsulfate at 65° C for 1.5 hours. Membrane filters were autoradiographed on Kodak X-omat film for up to 24 hours.

High specific activity 5′-α^{35}S-deoxyadenosine triphosphate (>1000 Ci/mmol) and 5′-α^{32}P-deoxycytidine triphosphate (>3000 Ci/mmol) were obtained from Amersham (Amersham, United Kingdom). Plasmid pGEM4Z was obtained from Promega. All reagent grade chemicals were obtained from Sigma Chemical (St. Louis).

Results

Isolation and characterization of human BeWo 17β-estradiol dehydrogenase cDNA. The screening of 0.6×10^6 plaques from a cDNA library derived from a human BeWo choriocarcinoma cell line with an 1100 base pair human placental 17β-estradiol dehydrogenase cDNA probe yielded 15 positive signals. Southern blot analysis confirmed that the cDNA sequence from the BeWo cell line corresponding to the human placental cDNA was contained in a 1.3 kb *Eco*RI fragment (data not shown). The 1.3 kb insert from this cDNA clone was isolated and the entire nucleotide sequence was determined (Fig. 1). Comparison of the BeWo 17β-estradiol dehydrogenase cDNA with the placental cDNA sequence established previously[8] revealed >98% homology, with complete homology in the substrate and cofactor binding domains.

Isolation and characterization of human Jar 17β-estradiol dehydrogenase genomic clone. Screening of 0.6×10^6 plaques from a Jar choriocarcinoma genomic library generated three positive signals. A single 6.0 kb *Kpn* I fragment contained the entire cDNA sequence

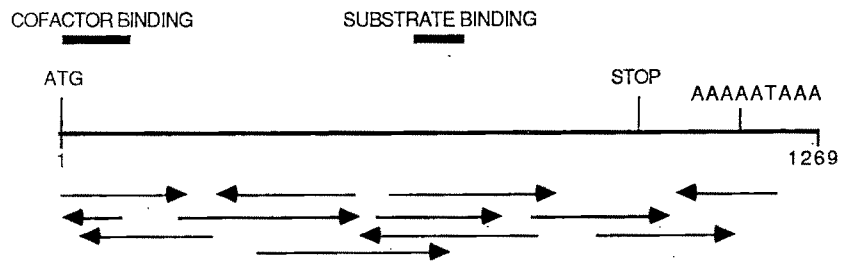

Fig. 1. Sequencing strategy for the BeWo 17β-estradiol dehydrogenase cDNA clone. Sequencing was carried out by a modified dideoxy nucleotide technique with ^{35}S-labeled deoxyadnenosine triphosphate. Universal primers and specific synthetic oligonucleotides were used as primers for sequencing reactions. The relative locations of steroid and cofactor binding sites and polyadenylation site are identified.

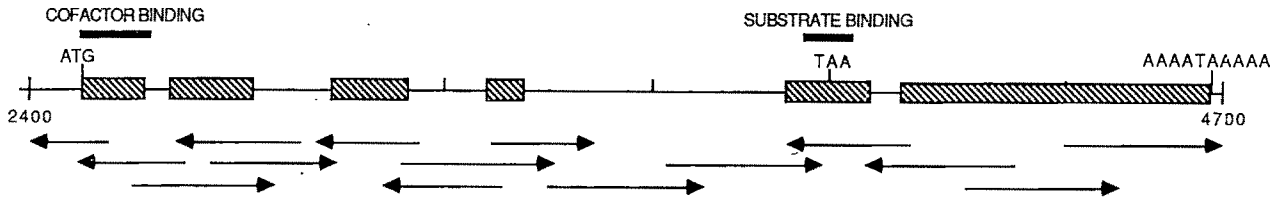

Fig. 2. Characterization and sequencing for the Jar 17β-estradiol dehydrogenase gene. The six encoding exons are represented by *striped boxes*. Nontranscribed regions are represented by *solid lines*. Relative locations of the substrate and cofactor binding sites are identified. ATG start codon and premature TAA stop codon are also noted.

of the BeWo 17β-estradiol dehydrogenase as determined by Southern blot analysis (data not shown). This *Kpn* fragment was placed into the plasmid vector pGEM4Z and sequenced by dideoxy chain termination. The human gene encoding for 17β-estradiol dehydrogenase contains at least six exons and spans approximately 2.4 kb of human genomic DNA (Fig. 2). The protein-encoding exons range in size from 72 to 555 base pair, whereas introns vary in length from 70 to 497 base pair. The nucleotide sequences surrounding intron-exon junctions correspond to those predicted by cDNA comparison, as well as published consensus sequences.[13] Each donor splice site begins with GT, whereas each acceptor splice site ends with AG. A consensus polyadenylation sequence (AATAAA), which delineates the 3′ end of the sixth and final exon of this gene, is also identified.

A composite nucleotide sequence representing the putative Jar cDNA encoding 17β-estradiol dehydrogenase was deduced from the genomic sequence and was compared with the BeWo choriocarcinoma cDNA (Fig. 3). Differences between the BeWo cDNA and Jar-deduced cDNA fell into three general categories. The first category included random point changes that were seen throughout the cDNA sequences. Second, two major deletions were noted in the Jar-deduced cDNA, a 9 base pair deletion within exon 3 and a 24 base pair deletion corresponding to the midportion of exon 6. The third important difference was a single point change from cytosine to thymine midway through exon 5, which would act to produce an in-frame TAA stop codon in the Jar gene product.

RNA blot hybridization analysis. To perform Northern blot analysis for the evaluation of transcription of the 17β-estradiol dehydrogenase gene in the Jar cell line, total RNA was extracted from BeWo and Jar cells as described in the Methods section. For a noncultured, nonneoplastic control, RNA from luteinized granulosa cells was also extracted and analyzed. The Northern blot was probed with the previously described 1100 base pair fragment constructed from the 3′ end of the BeWo cDNA (Fig. 4). A single dark band was found in the BeWo lane corresponding to an RNA of approximately 1.3 kb, which is identical to results obtained when analyzing placental RNA. In the Jar lane, a similar 1.3 kb RNA is also present. Slightly reduced density of this signal in the Jar lane may reflect modestly decreased homology of the Jar mRNA to the placental RNA. Two radiolabeled bands are noted in the granulosa cell lane—one corresponds to the placental 17β-estradiol dehydrogenase RNA of 1.3 kb and the second corresponds to a larger homologous RNA of 2.1 kb.

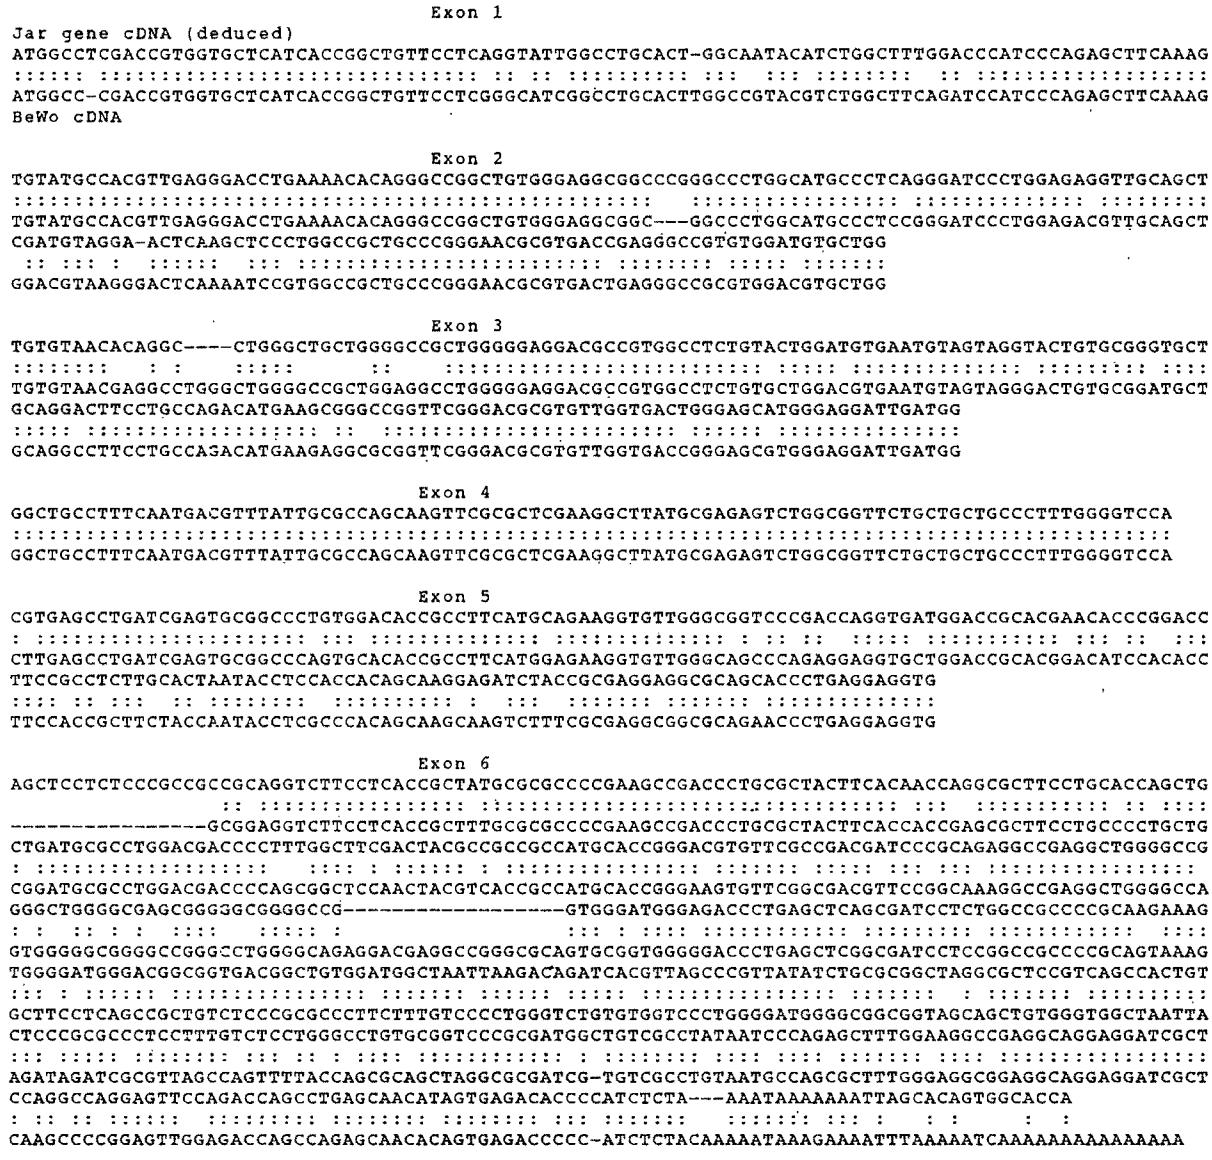

Fig. 3. Comparison of the nucleotide sequence of the BeWo cDNA encoding 17β-estradiol dehydrogenase *(bottom)* with the cDNA sequence deduced from the 17β-estradiol dehydrogenase gene from a Jar cell line *(above)*. Assignment of putative exons was made on the basis of locations of consensus donor and acceptor splice sequences and the known sequence of BeWo and placental cDNAs. *Colons* between sequences indicate identity of bases at respective positions in the sequence.

Comment

We isolated and sequenced a cDNA clone encoding 17β-estradiol dehydrogenase from the BeWo choriocarcinoma cell line. A genomic DNA sequence arising from DNA isolated from the Jar choriocarcinoma cell line has also been established. This gene consists of six exons and spans approximately 2.4 kb of genomic DNA. By comparing the BeWo cDNA with Jar genomic DNA, we were able to deduce a Jar cDNA encoding 17β-estradiol dehydrogenase. The intron-exon splice junctions predicted by this data and by the homology of the Jar cell line to the human placental cDNA are in complete agreement with the AG-GT rule.[13]

On alignment of the BeWo cDNA with the Jar-deduced cDNA there is approximately 77% nucleic acid homology between the two putative mRNA species. Differences between the two may be grouped into three categories: nonsignificant point differences, segmental deletions, and a point change from cytosine to thymine within a single critical codon in exon 5. When these

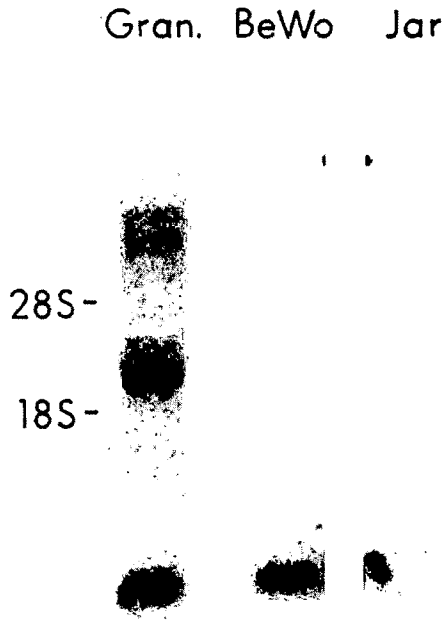

Fig. 4. DNA/RNA hybridization (Northern blot) analysis of luteinized granulosa, BeWo, and Jar cells. The Northern blot was probed with a ^{32}P-labeled 1100 base pair cDNA fragment from 3′ end of a BeWo cDNA clone. The lowest molecular weight band, present in all three cell types, represents a 1.3 kb DNA fragment. There is a second 2.1 kb species of mRNA clearly identified in the granulosa lane. Higher molecular weight material present in the granulosa cell lane likely represents artifact.

two sequences are translated into their respective amino acid sequences, the Jar-deduced cDNA has an in-frame stop codon rather than the glycine encoded by the BeWo cDNA. Of greatest significance, this termination signal would occur in the middle of the substrate binding domain of the Jar 17β-estradiol dehydrogenase enzyme. This pattern of mutations has been described in a variety of paired genes in which the phenomenon of gene complementation has occurred, including the gene for the human steroid-converting enzyme 21-hydroxylase.[14-16] On the basis of this data we hypothesized that two genes for 17β-estradiol dehydrogenase exist in the human genome but that only one of these genes (the complement) survived intact into the genome of the Jar cell line. The et al.[17] recently identified two apparently complementary tandemly arranged 17β-estradiol dehydrogenase genes within the human genome, providing partial confirmation to this theory.

Evaluation of gene expression in the BeWo and Jar cell lines was performed by DNA-RNA hybridization analysis. Probing Northern blots of RNA extracts from both BeWo and Jar cells with an 1100 base pair fragment constructed from the cDNA of BeWo, we consistently found mRNA corresponding to 1.3 kb in each cell line. This is identical to results obtained when analyzing RNA.[8] In contrast, RNA extracts from luteinized granulosa cells exhibited not only a 1.3 kb signal, but also a larger, distinct RNA of 2.1 kb. These granulosa cells, although not cultured, were obtained from patients undergoing ovarian hyperstimulation via human menopausal gonadotropins and human chorionic gonadotropin. DNA-RNA hybridization analysis of BeWo cells under less stringent conditions also reveals this larger 2.1 kb mRNA, but as a minor component (data not shown). We have no explanation for the second form of 17β-estradiol dehydrogenase message, although it would be tempting to propose a regulatory role for what we may assume is an alternately spliced RNA product. Experiments are under way in our laboratory to evaluate the less likely possibility that one of these messages may also represent the transcription product of the complementary, inactive gene.

In summary, we compared the molecular biology of 17β-estradiol dehydrogenase in two choriocarcinoma cell lines, BeWo and Jar, with that of the human placenta. The data presented herein indicate that two genes for 17β-estradiol dehydrogenase exist in the human genome. The predicted amino acid sequence based on the BeWo cDNA is essentially identical to that predicted from the established placental cDNA. On the other hand, the deduced Jar cDNA has major differences, including a premature stop signal interrupting the predicted amino acid sequence in the area of the substrate binding site. This suggests that only a single gene for 17β-estradiol dehydrogenase has survived intact into the Jar genome, that this gene does not produce an enzymatically active protein product, and that the absence of an intact complementary gene may account for the lack of 17β-estradiol dehydrogenase activity in this choriocarcinoma cell line.

We acknowledge Patricia B. McEwen and Harold F. Sims for their continuing encouragement and superior technical assistance.

Bound volumes available to subscribers

Bound volumes of the AMERICAN JOURNAL OF OBSTETRICS AND GYNECOLOGY are available to subscribers (only) for the 1990 issues from the Publisher, at a cost of $56.00 ($79.00 international) for Vol. 162 (January-June) and Vol. 163 (July-December). Shipping charges are included. Each bound volume contains a subject and author index and all advertising is removed. Copies are shipped within 60 days after publication of the last issue in the volume. The binding is durable buckram with the JOURNAL name, volume number, and year stamped in gold on the spine. *Payment must accompany all orders.* Contact Mosby–Year Book, Inc., Circulation Department, 11830 Westline Industrial Drive, St. Louis, Missouri 63146-3318, USA; phone (800) 325-4177, ext. 7351.

Subscriptions must be in force to qualify. Bound volumes are not available in place of a regular JOURNAL subscription.

Antiprogestin treatment decreases midluteal luteinizing hormone pulse amplitude and primarily exerts a pituitary inhibition

Donna Shoupe, MD,[a] Daniel R. Mishell, Jr, MD,[a] Gregory Fossum, MD,[a] Bradford L. Bopp,[a] Irving M. Spitz, MD,[b] and Rogerio A. Lobo, MD

Los Angeles, California, and New York, New York

Mifepristone (RU 486), a synthetic steroid with antiprogesterone receptor activity, was given with and without naloxone hydrochloride to six women in the midluteal phase to investigate the role of progesterone in the modulation of endogenous opioid activity and the secretion of luteinizing hormone and cortisol. Subjects were evaluated during four sequential monthly admissions during which multiple blood samples were obtained every 15 minutes for 8 hours. Patients were studied during a baseline cycle, after administration of RU 486 alone (100 mg/day), naloxone with RU 486, and naloxone alone. After administration of RU 486 there was a significant decline in total luteinizing hormone secretion ($p < 0.01$) and luteinizing hormone pulse amplitude ($p < 0.05$), but compared with baseline there was no significant change in luteinizing hormone pulse frequency. After infusion of naloxone there was a significant increase in mean luteinizing hormone values ($p < 0.05$) and luteinizing hormone pulse frequency ($p < 0.01$) but no change in pulse amplitude. There was no significant difference in mean luteinizing hormone values or luteinizing hormone pulse amplitude and frequency between administration of RU 486 and naloxone plus RU 486. Administration of naloxone alone, RU 486 alone, and RU 486 plus naloxone caused a significant increase in cortisol as compared with baseline cycles ($p < 0.05$). These data further support the notion that progesterone is important in the control of luteinizing hormone secretion and suggest that progesterone may primarily influence luteinizing hormone pulse amplitude and pituitary release of luteinizing hormone during the luteal phase. (Am J Obstet Gynecol 1990;163:1982-5.)

Key words: RU 486, pituitary effect

In a normal cycle, rising levels of progesterone in the luteal phase of the menstrual cycle is associated with a changing pattern of luteinizing hormone (LH) secretion. LH pulses change from being of high frequency and low amplitude during the follicular phase to pulses of high amplitude and low frequency during the luteal phase.[1] The frequency of LH pulses declines progressively during the luteal phase and correlates with the cumulative progesterone exposure.[1]

Mifepristone (RU 486), a synthetic steroid that binds to progesterone receptors and blocks the action of progesterone, appears to have multiple effects on the hypothalamic-pituitary-ovarian axis. When administered in the follicular phase of the menstrual cycle it blocks ovulation and results in a decline in estradiol[2, 3] and LH[4] levels during treatment. Addition of RU 486 to cultured human granulosa cells causes a decline in progesterone[5] secretion into the media whereas its administration in the midluteal phase in some subjects is associated with a decline both in LH levels[6, 7] and luteolysis.[8-10] In addition, RU 486 binds to the glucocorticoid receptor even more strongly than dexamethasone.[11] The antiglucocorticoid action of RU 486 appears to occur during periods of active adrenocorticotropic hormone (ACTH) secretion.[12, 13]

Endogenous opioids appear to play an important role in the determination of LH pulsatility by inhibiting hypothalamic gonadotropin-releasing hormone secretion.[14] This inhibitory action is thought to be modulated by ovarian steroids[15] and the maximum suppression occurs during the high-estrogen and high-progesterone phases of the cycle. Infusion of naloxone during the luteal phase in a normal subject results in the uncoupling of this inhibitory activity, an increase in LH pulse frequency, and a decline in pulse amplitude.[16]

Our purpose was to investigate the effects of an an-

tiprogestin given in the midluteal phase on LH pulsatility and cortisol secretion, and to investigate this interaction with and without opioid blockade.

Material and methods

Six women, ages 21 to 33 years, with cycle lengths that averaged 28 ± 2 days, were evaluated for six consecutive cycles. Each woman was within 20% of ideal body weight and had a documented serum progesterone level >5 ng/ml in the cycle before entry to this study. During the study months, blood was obtained on day 10 and daily thereafter until the LH surge was detected by daily radioimmunoassay. During all four study cycles, patients were admitted to the Clinical Research Center at 7:00 AM, 6 to 9 days after the LH surge, and blood samples were obtained every 15 minutes for 8 hours. Before the first study admission, no medication was given. During the following cycle, RU 486 at a dose of 50 mg twice a day (50 mg tablets, supplied by Roussel Uclaf, Romainville, France) was begun 3 days before admission. The last pill was taken in the morning of admission between 6:00 and 7:00 AM.

During the fourth cycle, RU 486 was administered as in cycle 2 with the addition of a naloxone infusion. During the sixth cycle, naloxone 2 mg/hour beginning at 8:00 AM was infused alone. Two baseline blood samples were obtained before the naloxone infusion. The third and fifth cycles were rest cycles, as the patients were not given medication and no blood sampling occurred.

Blood samples were allowed to clot and sera were separated and stored at −20° C until assayed for LH, estradiol, progesterone, and cortisol by previously described methods.[2, 6] Intra- and interassay coefficients of variation of the LH assay were <6% and <12%, respectively. Cortisol was measured in two baseline samples 15 minutes apart, and then hourly. All samples from an individual subject were measured in a single assay.

Statistics. Pulse frequency and amplitude were calculated with a computer program[17] based on the criteria described by Santen and Bardin.[18] A pulse was considered significant if there was an increase in LH over the mean of two baseline values that exceeded twice the interassay coefficient of variation. Pulse amplitude was defined as the absolute difference in hormone concentrations between peak and nadir values.

Other statistical comparisons were carried out with the assistance of the Clinfo computer program with analysis of variance and the Student t test. Values are expressed as mean ± SE.

Results

Baseline progesterone and estradiol levels before infusion during the first cycle were 13.4 ± 4.5 ng/ml and 135.2 ± 15.6 pg/ml, respectively, and were not significantly different during the other treatment months (Table I).

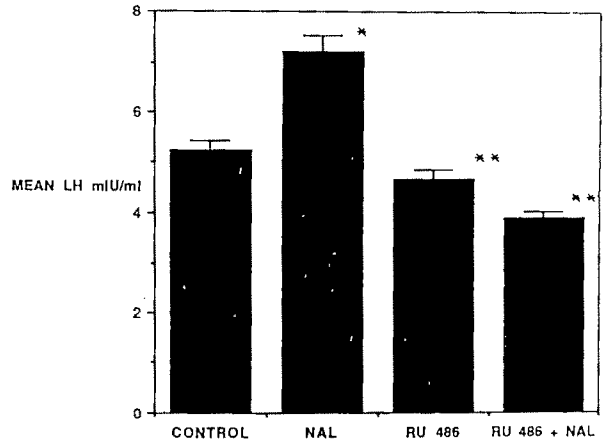

Fig. 1. Mean LH values ± SEM in following groups: control, naloxone *(NAL)* alone, RU 486, and RU 486 plus naloxone. *$p < 0.05$ from baseline; **$p < 0.05$ from other three groups.

Table I. Progesterone and estradiol levels before infusion

	Progesterone (ng/ml)	*Estradiol (pg/ml)*
Baseline	13.4 ± 4.5	135.2 ± 15.6
RU 486	14.0 ± 8.7	110.2 ± 48.3
RU 486 + naloxone	14.5 ± 8.6	136.0 ± 73.9
Naloxone	11.2 ± 10.1	111.3 ± 76.5

No significant differences.

When analyzed by analysis of variance, mean LH values during the sampling period were significantly lower after administration of RU 486 alone and RU 486 plus naloxone compared with baseline ($p < 0.05$) (Fig. 1). Mean LH values after infusion of naloxone alone (7.2 ± 0.3 mIU/ml) increased significantly ($p < 0.05$) compared with all other sampling periods. There was no difference in mean LH values between administration of RU 486 alone and RU 486 with naloxone.

During the baseline cycle there were 1.75 ± 0.2 LH pulses with a mean pulse amplitude of 5.2 ± 0.5 mIU/ml during the 8-hour sampling period. After administration of RU 486 there was a significant decline in LH pulse amplitude ($p < 0.05$), whereas no significant change occurred in LH pulse frequency as noted above. No significant changes occurred in LH pulse frequency in any group except with infusion of naloxone in which LH pulse frequency increased to 2.7 ± 0.4 ($p < 0.05$). The administration of RU 486 with naloxone also decreased LH pulse amplitude ($p < 0.05$), whereas increases in LH pulse amplitude were evident with infusion of naloxone alone (Table II).

Table II. LH pulsatility in 8 hours during four different treatment periods

	No. of pulses	*Pulse amplitude mIU/ml*
Baseline	1.75 ± 0.25	5.2 ± 0.5
RU 486	0.9 ± 0.2	3.1 ± 0.8*
RU 486 + naloxone	1.5 ± 0.3	3.0 ± 0.4*
Naloxone	2.7 ± 0.4*	6.5 ± 0.9

Mean ± SE.
*$p < 0.05$ compared with baseline.

Table III. Mean cortisol values during four sampling periods

	Cortisol µg/dl
Baseline	11.0 ± 1.5
RU 486	17.0 ± 1.7*
RU 486 + naloxone	16.0 ± 1.7*
Naloxone	16.0 ± 1.4*

*$p < 0.05$ compared with baseline.

Figs. 2 and 3 show the LH values in a typical patient during the control cycle, after treatment with RU 486 with and without naloxone and after infusion of naloxone alone.

Mean cortisol values were significantly higher than baseline in all treatment groups after RU 486 alone, RU 486 plus naloxone, and naloxone alone (Table III).

Comment

Administration of RU 486 before ovulation in normally cycling women causes ablation of the normal LH–follicle-stimulating hormone surge with lowering of serum estradiol and progesterone.[2] When given in the midluteal phase, high doses of RU 486 (between 200 and 800 mg) cause luteolysis and a decline in estradiol within 24 hours in up to 35% of subjects.[5] In this study, treatment in the midluteal phase with 100 mg RU 486 for 3 days resulted in no significant changes in estradiol or progesterone.

Because progesterone has been shown to increase LH pulse amplitude and decrease the gonadotropin-releasing hormone–mediated pulses in the luteal phase of the normal menstrual cycle,[19] administration of an antiprogestin in the midluteal phase would be expected to decrease LH pulse amplitude and increase pulse frequency. In this study, there was a decline in LH pulse amplitude and mean LH secretion after administration of RU 486. However, we noted a decrease in LH pulse frequency after RU 486, although this was not significant. This discrepancy may be a result of the inherent difficulties involved in accurately detecting the presence of LH pulses when LH levels are low. Interpretation of LH pulse frequency data is also limited because of the low number of pulses that occur in the luteal phase. Previous work is in agreement with our findings in that a slight but nonsignificant increase in LH pulse frequency was found to occur along with a significant decline in pulse amplitude after administration of RU 486 in the midluteal phase.[7] Alternatively, these data may suggest that progesterone exerts a primary influence on LH pulse amplitude and the failure to detect changes in LH pulse frequency signifies the lack of a direct hypothalamic effect during the luteal phase.

It is most plausible that the changes in LH secretion and LH pulse amplitude, specifically, are a result of a direct pituitary effect of RU 486. This finding is sup-

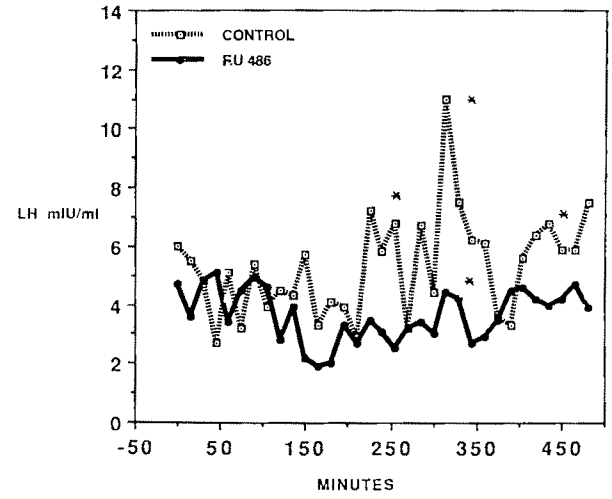

Fig. 2. LH values in typical subject during 8 hours in control cycle and after administration of RU 486. *Indicates pulses.

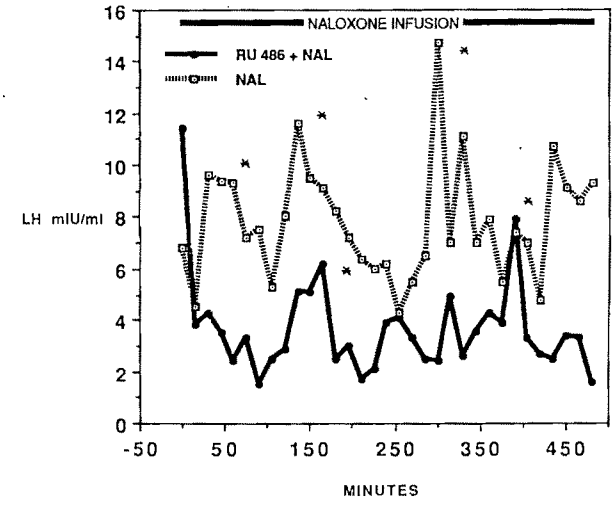

Fig. 3. LH values in typical subject during 8-hour naloxone *(NAL)* infusion with and without prior administration of RU 486. *Indicates pulses.

ported by previous work that shows that RU 486 impairs the pituitary response to gonadotropin-releasing hormone.[7, 20] RU 486 alone did not inhibit LH pulse frequency, suggesting that progesterone may not have a direct influence on hypothalamic gonadotropin-releasing hormone discharge. Inasmuch as naloxone alone (opioid blockade) increased LH pulse frequency, this natural opioid effect may be in part independent of the effect of progesterone. Results of administration of RU 486 in combination with naloxone were not different from those of RU 486 when used alone.

The antiglucocorticoid effect of RU 486 is well known[11] and the increase in cortisol after administration of RU 486 is thought to be mediated by increases in ACTH.[11] The increase in cortisol after administration of naloxone alone has also been reported by our group.[21] There is evidence that β-endorphin may regulate cortisol secretion by attenuating the cortisol response to exogenous ACTH and may also decrease the pituitary secretion of ACTH.[22, 23] However, the addition of naloxone and RU 486 were neither additive nor inhibitory to cortisol, suggesting that these two mechanisms of increasing ACTH and cortisol release may be independent.

These data support a direct pituitary action of RU 486 in decreasing LH pulse amplitude and further suggest that the effect of progesterone on LH pulse amplitude may not be mediated through endogenous opioids. These data further suggest that the inhibitory hypothalamic effect of opioid peptides may not be fully dependent on progesterone.

Luteal insufficiency: Correlation between endometrial dating and integrated progesterone output in clomiphene citrate–induced cycles

Bryan R. Hecht, MD,[a] Wadi A. Bardawil, MD,[c] Firyal S. Khan-Dawood, PhD,[b] and M. Yusoff Dawood, MD[b]

Chicago, Illinois, and Houston, Texas

Midluteal phase endometrium was histologically dated with midcycle luteinizing hormone surge time in 29 cycles from 10 parous women during untreated cycles (control) and treatment with clomiphene citrate 50 mg and 150 mg daily on days 5 through 9. Integrated progesterone output for 7 days after luteinizing hormone surge calculated from the daily plasma progesterone levels was 66.6 ± 9.8 ng/ml in the control group compared with 117.5 ± 18.6 ng/ml for clomiphene citrate 50 mg treatment and 152.1 ± 11 ng/ml for clomiphene citrate 150 mg treatment ($p \leq 0.05$). Only one cycle (clomiphene citrate 150 mg) had an out-of-phase endometrium and a significantly reduced integrated progesterone output of 28 ng/ml. All other cycles showed synchronous endometrial maturation. We conclude that luteal insufficiency as a result of clomiphene citrate treatment in ovulatory women is infrequent and is more likely to be a result of functional outcome of a relative lack of luteal phase progesterone output. (AM J OBSTET GYNECOL 1990;163:1986-91.)

Key words: Clomiphene citrate, luteal phase defect, progesterone, endometrial dating, endometrial asynchrony

Luteal phase defect and conception failure occur in some cycles in which clomiphene citrate has been administered for induction or augmentation of ovulation.[1, 2] The incidence and mechanisms of clomiphene citrate–induced luteal phase defect remain debatable. Deficient luteal progesterone production or a direct adverse effect of clomiphene on endometrial responsiveness are both mechanisms that could be responsible for producing this clinical phenomenon.

Histologic diagnosis of luteal phase defect is usually made by comparison of the actual endometrial histologic findings with those expected on the basis of the onset of menses after the biopsy.[3] Both clinical and histologic evidence suggest that use of this "next menses" criteria may not provide the most precise relationship to the actual time of ovulation. Thus, imprecise interpretation of the endometrial histology can occur with such criteria because the true postovulatory luteal age is not known. The use of the midcycle luteinizing hormone surge is a superior reference point for histologic dating of the endometrium.[4] To further define the effect of clomiphene citrate on luteal phase physiology, we conducted a controlled study in normal ovulatory women to compare (1) the actual luteal histology with the expected findings on the basis of the midcycle serum luteinizing hormone (LH) surge as well as with integrated progesterone output on the basis of daily plasma progesterone levels, and (2) the effect of high and low doses of clomiphene citrate on luteal phase endometrial development.

Material and methods

The study was approved by the Institutional Review Board of the University of Illinois at Chicago, where the study was conducted. Ten normal, fertile women with regular ovulatory menstrual cycles volunteered to participate and gave informed consent. All subjects had previously undergone tubal ligation or were using barrier contraceptive methods. The clinical characteristics of these subjects and treatment cycles have been reported by us in previous publications.[5, 6] The mean age was 30.3 ± 1.1 years (±SEM), weight was 77.3 ± 5.4 kg, parity was 2.4 ± 0.4, and the normal control menstrual cycle length was 28.5 ± 1.1 days.

Medication protocol. Eight subjects were studied for three consecutive menstrual cycles whereas two were studied for three nonconsecutive cycles. The first cycle

was a control cycle during which the subjects did not receive medication. In the second cycle, 50 mg clomiphene citrate was given daily on days 5 through 9 of the cycle and in the third cycle, 150 mg clomiphene citrate (50 mg three times a day) was given on days 5 through 9.

Basal body temperature was recorded by each subject for all cycles studied. The first-voided urine samples were collected daily, beginning on cycle day 11 and continued until an LH surge was identified or a sustained basal body temperature rise was evident. Daily peripheral heparinized venous blood samples were obtained between 8:00 AM and 10:00 AM beginning on cycle day 11. The plasma was separated and stored at −20° C until assayed. Plasma LH was measured by a specific double-antibody radioimmunoassay.[7] Plasma progesterone was measured by a specific radioimmunoassay as previously described with an antibody raised against progesterone-11-oxime bovine serum albumin conjugate.[8] To reduce interassay variability, all blood samples from the same patient were performed in the same assay for each hormone.

Endometrial biopsy specimens were obtained 8 to 12 days after the urine LH surge. Subsequently when the plasma LH levels were determined, midcycle plasma LH surge to endometrial biopsy intervals were 7 to 12 days, with a mean interval of 10.4 ± 0.2 days for the control cycle, 10.7 ± 0.4 days for the 50 mg clomiphene citrate treatment cycle and 10.8 ± 0.1 days for the 150 mg clomiphene citrate cycle. Ibuprofen 800 mg was given orally 1 hour before the endometrial biopsy, which was performed under a paracervical block. The uterine cavity was systematically and thoroughly curetted to obtain as much tissue as possible. Endometrial tissue was immediately rinsed in normal saline solution to remove blood and debris and a random piece was taken for histologic studies. The remaining tissue was used for steroid hormone receptor measurements.[5] Endometrial tissue was processed for routine hematoxylin and eosin staining and was subsequently randomly read and interpreted by a gynecologic pathologist (W.A.B.) who was unaware of the treatment given. Histologic dating was performed according to the criteria of Noyes et al.,[3] but the interval from the midcycle plasma LH surge to the day of biopsy (not the onset of next menses) was then used to calculate the expected dating.

Integrated progesterone values were calculated from the area under the curve of daily plasma progesterone with the trapezoidal rule for the first 7 days of the luteal phase (LH + 0 to LH + 7). Because the earliest biopsy performed in any cycle was on LH + 7, this 7-day interval was chosen to include the maximum number of days from surge to biopsy that could be compared in all cycles.

Data are expressed as mean ± SEM. Means were compared with analysis of variance and the nonpaired Student t test. A p value >0.05 was considered not significant.

Results

Clinical findings. All cycles (control and treatment) studied were ovulatory as determined by identification of an LH surge, biphasic basal body temperature recordings, elevated luteal phase plasma progesterone concentrations, and/or the presence of secretory endometrium.

Endometrial histology. Endometrium was not available for dating in one (clomiphene citrate 50 mg) of 30 cycles studied. All control (n = 10) and clomiphene citrate 50 mg cycles (n = 9) showed endometrial maturation within 48 hours of the chronologically expected date, calculated from the number of days after the LH surge on which the biopsy was obtained. One clomiphene citrate 150 mg treatment produced endometrium out of phase by 4 days (day 20 when day 24 was expected).

Integrated progesterone. In control cycles, integrated progesterone (mean ± SEM) was 66.6 ± 9.8 ng/ml (n = 7), compared with 117.5 ± 18.6 ng/ml (n = 8) for clomiphene citrate 50 mg and 152.1 ± 11 ng/ml (n = 8) for clomiphene citrate 150 mg treatment cycles (Fig. 1). In the clomiphene citrate 150 mg treatment cycle with out-of-phase endometrium, integrated progesterone was only 28 ng/ml. Fig. 2, *A* and *B* and Fig. 3, *A* and *B* show representative samples of in-phase and out-of-phase endometrium and their corresponding daily and integrated plasma progesterone values in two different women, each after treatment with 150 mg/day of clomiphene. According to customary criteria,[3] the histology in Fig. 2, *B* would be read as "day 23" in agreement with the expected histology on the basis of the LH surge (LH surge in an ideal cycle being day 13 and endometrial biopsy performed on LH + 10, making it day 23). The corresponding integrated progesterone value in this cycle was 146.9 ng/ml. The endometrial sample shown in Fig. 3, *B* was obtained on LH + 11 with an expected finding of "day 24." This biopsy was interpreted as "day 20," 4 days out of phase. The corresponding integrated progesterone value was only 28 ng/ml.

Thus only one of 19 cycles showed true luteal phase inadequacy during clomiphene citrate treatment (approximately 5%).

Comment

Because of the possibility that treatment with clomiphene citrate may directly or indirectly affect endometrial preparation and suitability for implantation, we examined the effect of low and high doses of clomiphene citrate on luteal phase endometrial histology

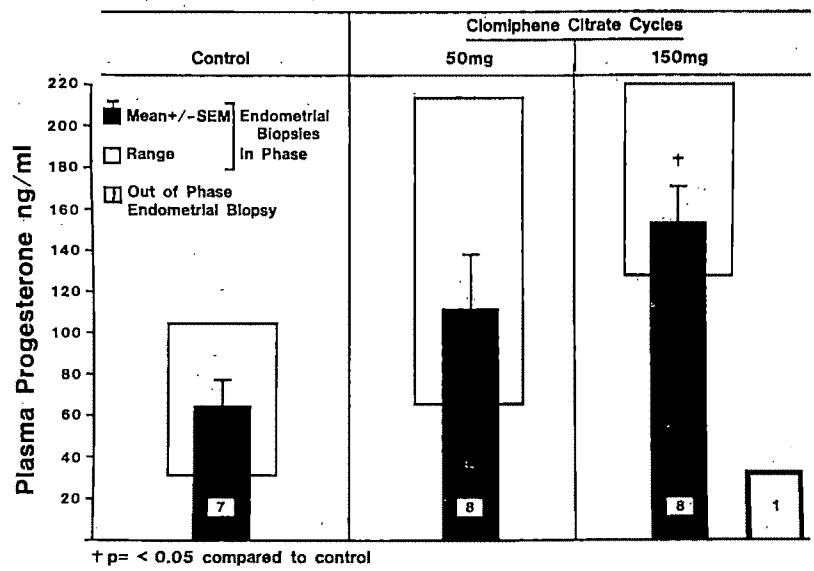

Fig. 1. Mean ± SEM integrated progesterone output for 7 days after midcycle plasma LH surge in control cycles (no treatment) and in clomiphene citrate 50 mg–treated and clomiphene citrate 150 mg–treated cycles in 10 parous women. Integrated progesterone output increased significantly during clomiphene citrate 150 mg treatment cycles ($p < 0.05$) but was significantly reduced in one cycle that had out-of-phase delayed endometrial histology.

in a group of normal ovulatory women. The use of normal ovulatory women should avoid other possible confounding factors that may cumulatively affect the endometrium in infertile women besides the use of clomiphene citrate. At a daily dose of 50 mg given from the fifth through the ninth day of the cycle, clomiphene citrate treatment did not affect histologic evidence of periimplantation phase endometrial maturation. However, at 150 mg daily, clomiphene citrate did produce one out-of-phase (delayed) endometrial biopsy with a corresponding low integrated progesterone output over the first 7 days of the luteal phase. In contrast, the remaining 150 mg clomiphene citrate–treated cycles had significantly higher integrated progesterone output compared with control cycles in the same women.

There is disagreement with regard to the sensitivity and reliability of endometrial dating by histology as described by Noyes et al.[3] Such dating is based on chronologic dating from the next menstrual period and assumes that all normal luteal phase lengths are 14 days—an assumption that is invalid.[9, 10] Only 27% of regular cycles had luteal phases of exactly 14 days whereas 31% had 12 days or fewer or 16 days or more.[10] The correlation of $r = 0.7$ between observers[4] and the interobserver variation of one day is also sufficient to cause a change in endometrial dating that would alter clinical management in 22% to 39% of the patients studied.[11] The intraobserver agreement of 24% and disagreement of >2 days in 10% of the same specimens read twice separately also attest to the subjectivity and variability of endometrial dating.[12] Furthermore, even when all the variables described in the technique of Noyes et al.[3] are used, Li et al.[12] have shown that the dating is imprecise and not as reliable as it is made out to be. Several investigators[9, 13, 14] have advocated the need to use morphometric analysis for the histologic dating to obtain more precise and valid interpretation. Only 5 of the 17 morphometric measurements examined have been found to be necessary for an accurate histologic dating.[13] The five predictive morphometric variables are the number of mitoses per 1000 gland cells, the amount of secretion in the gland lumen, the volume fraction of gland occupied by gland cell, the amount of pseudostratification of gland cells, and the amount of stromal predecidual reaction. We used the day of the plasma LH surge as the temporal reference point to estimate the expected histologic finding rather than the onset of the next menses. The timing of the LH surge is certainly more closely defined to the time of ovulation than to the next menstrual period and therefore will give a more precise and valid dating of the endometrium. Li et al.[4] found chronologic dating of the endometrium with the next menstrual period gave a larger variance than did use of midcycle serum LH, which reduced the incidence of out-of-phase endometrium from 42% to 10%.

Whereas endometrium obtained as late as possible in the cycle may have a greater degree of progesterone biologic effect and therefore is preferred by some pathologists for dating, others found the histologic features are more variable in the late luteal phase with

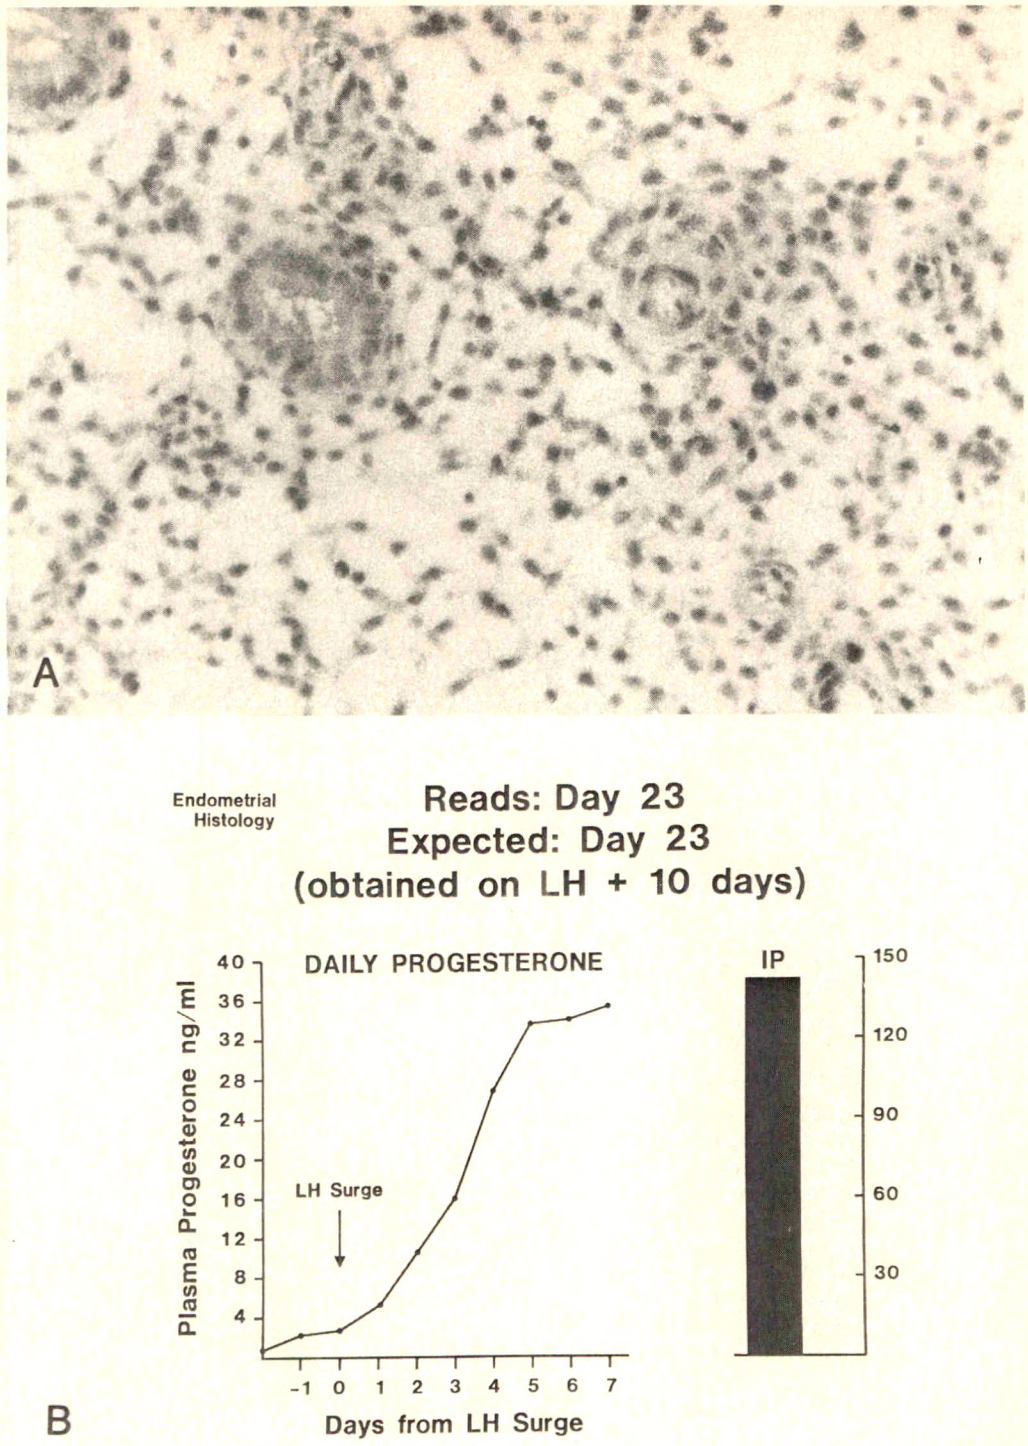

Fig. 2. Histologic appearance of in-phase endometrium **(A)** with corresponding integrated plasma progesterone value **(B)** for subject who received 150 mg clomiphene citrate daily for days 5 through 9 of cycle. Integrated plasma progesterone *(IP)* was calculated for 7 days after plasma LH surge.

intraobserver exact agreement less in the second half of the luteal phase than in the first half of the luteal phase.[12] We elected to perform the endometrial biopsies in the midluteal phase 7 to 10 days after the midcycle plasma LH surge and to specifically examine this window of time around implantation when histologic asynchrony or abnormalities would likely affect successful implantation. Furthermore, the optimum dose effect of progesterone should have been exerted on and the endometrium sufficiently transformed to be consistent

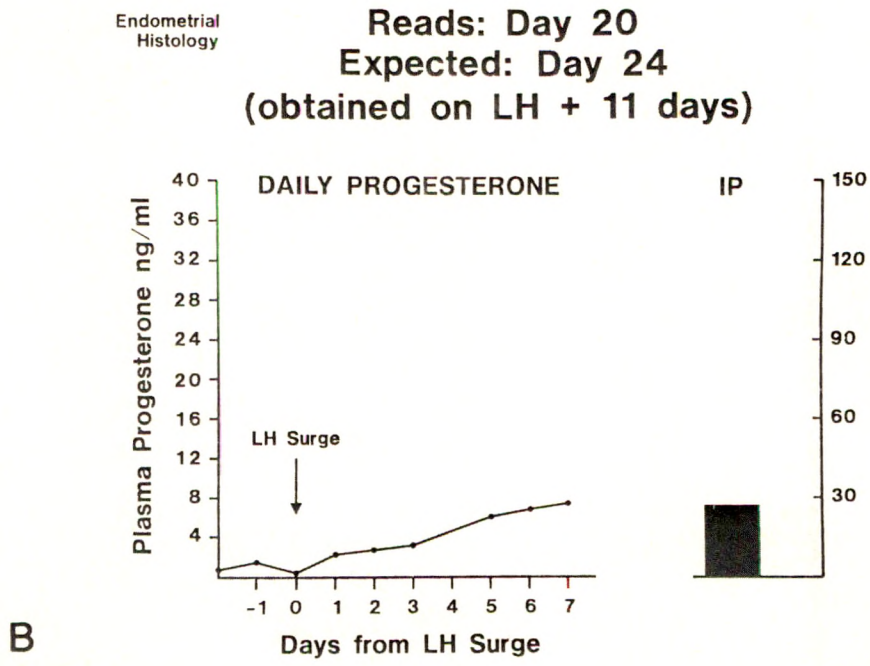

Fig. 3. Histologic appearance of out of phase endometrium **(A)** with the corresponding integrated plasma progesterone *(IP)* value **(B)** for subject who received 150 mg clomiphene citrate daily for days 5 through 9 of cycle. Integrated plasma progesterone *(IP)* was calculated for 7 days after plasma LH surge.

with preparation for successful implantation. Because of this consideration and also the slight variability in the chronologic timing after the plasma LH surge, we chose the integrated progesterone output on the basis of the first 7 days of the luteal phase after the midcycle LH surge. This would also be consistent with the time when implantation occurs. With use of the above criteria, we found that only 1 of 19 cycles (5%) treated

with clomiphene citrate produced a true luteal phase abnormality as a result of deficient progesterone. This cycle had a significantly reduced integrated progesterone output as well as an out-of-phase endometrium (delayed 4 days). The endometrial estrogen and progesterone receptors were normal,[5] and therefore the out-of-phase endometrium was a result of inadequate luteal progesterone output leading to deficient progesterone effect on the endometrium.

Failure to recognize the need to consider the cumulative effect of continuing luteal progesterone output on the endometrium and the wide variability in peripheral progesterone levels throughout the day, as well as throughout the luteal phase, has placed unnecessary emphasis on the significant correlation or lack thereof with peripheral progesterone levels. Area under the curve as reflected by integrated progesterone output calculated by the trapezoid method gives a closer reflection of the total amount of progesterone to which the endometrium has been exposed during the luteal phase up to that particular time and has been shown to be reliable in the assessment of luteal function.[15] Previous studies that found a high incidence or prevalence of luteal phase defects with clomiphene citrate treatment[16] were carried out in anovulatory or oligo-ovulatory women and used either endometrial dating with the criteria of Noyes et al.[3] or luteal phase single or up to three pooled or individual serum progesterone levels,[17] the pitfalls of which have been extensively mentioned.

From the present investigation with the use of chronologic endometrial dating with the midcycle plasma LH surge, area under the curve progesterone output, and data on endometrial estrogen and progesterone receptors,[5] we conclude that in ovulatory women, the incidence of luteal phase defects or inadequacy as a result of clomiphene citrate–induction of ovulation is low and probably is a result of inadequate luteal phase progesterone production.

Specific binding sites for insulin-like growth factor I in the ovarian stroma of women with polycystic ovarian disease and stromal hyperthecosis

Manubai Nagamani, MD, and Charles A. Stuart, MD

Galveston, Texas

Women with polycystic ovarian disease and hyperthecosis have hyperinsulinemia and insulin resistance. It is possible that insulin in supraphysiologic concentration exerts its steroidogenic action on ovarian stromal cells through insulin-like growth factor I receptors. We undertook this study to investigate whether the ovarian stroma of women with hyperthecosis has specific binding sites for insulin or insulin-like growth factor I. Ovarian stromal tissue was obtained from seven women with normal ovulatory cycles and from five women with hyperthecosis of the ovaries. Binding studies with insulin tagged with iodine 125 and insulin-like growth factor I tagged with iodine 125 revealed specific binding sites both for insulin and insulin-like growth factor I in the ovarian stroma. The binding of insulin tagged with iodine 125 in the ovarian stroma of women with hyperthecosis (3.4% ± 1.1% (±SE) per 100 μg protein) was significantly ($p < 0.04$) lower than that observed in normal premenopausal women (8.3% ± 1.6% per 100 μg protein). By contrast, the specific binding of insulin-like growth factor I tagged with iodine 125 in the ovarian stroma of women with hyperthecosis (7.1% ± 1.7% per 100 μg protein) was higher than that observed in the ovarian stroma from normal women (4.5% ± 1.7% per 100 μg protein), although the difference was not statistically significant. The affinity constants for these high-affinity receptors were similar (1.2 to 3.6 × 10^9 L/mol) in the two groups of women. These results indicate that (1) the ovarian stroma has specific binding sites both for insulin and for insulin-like growth factor I; (2) in women with hyperthecosis, the ovarian stroma has decreased binding sites for insulin but has normal concentrations of insulin-like growth factor I receptors; and (3) in women with hyperthecosis, stimulation of ovarian androgen synthesis by insulin may be mediated through the insulin-like growth factor I receptors. (Am J Obstet Gynecol 1990;163:1992-7.)

Key words: Insulin-like growth factor I receptors, insulin receptors, ovarian stroma, hyperthecosis, polycystic ovarian disease

Insulin resistance and hyperinsulinemia are often seen in association with ovarian hyperandrogenism.[1-3] A positive correlation between peripheral insulin levels and ovarian vein androgen levels has been observed in women with hyperandrogenism as a result of hyperthecosis of the ovaries.[4] In vitro studies indicate that insulin stimulates ovarian stromal androgen synthesis.[5] However, patients with hyperinsulinemia have extreme insulin resistance that is a result of either defective insulin receptors or a postreceptor defect.[6, 7] It is hard to explain how insulin exerts its steroidogenic action on the ovarian stroma in these women because its action in other target tissues is defective. It has been shown that insulin in high concentration is capable of binding to insulin-like growth factor I receptors.[8] It is possible that insulin, which is present in supraphysiologic concentrations in women with polycystic ovarian disease and hyperthecosis, exerts its steroidogenic action on the ovarian stromal cells through insulin-like growth factor I receptors.

We undertook this study to investigate whether normal ovarian stroma has specific binding sites for insulin-like growth factor I and insulin and whether the number of these receptors is increased or decreased in women with hyperthecosis.

Material and methods

Patients. We obtained ovarian stromal tissue from seven normal premenopausal women undergoing hysterectomy for nonendocrine problems (myoma uterus, endometriosis, and cervical dysplasia). All of them had normal ovulatory cycles and had no hirsutism. The mean age was 39 years (range, 30 to 46 years) and the mean body weight was 160 pounds (range, 126 to 198 pounds). The fasting glucose and insulin levels were normal. Ovarian stromal tissue was also obtained from

five virilized women with a long history of hirsutism who were undergoing laparotomy. Clinical characteristics and endocrine studies of these five women are summarized in Tables I and II. All these women were obese, had anovulatory cycles, and had been hirsute for many years. All of them were nulliparous and had failed to ovulate with clomiphene citrate (Clomid). None had acanthosis nigricans. The testosterone levels were high. The dehydroepiandrosterone (DHEA) sulfate levels were in the low-normal range. After a high-carbohydrate (300 gm) diet was observed for 3 days, a standard oral glucose tolerance test was performed in all subjects around 8 AM. Blood samples for glucose and insulin levels were obtained before and hourly for 3 hours after oral glucose (75 gm) administration. Fasting insulin levels and insulin response to oral glucose were elevated in all patients whereas the glucose levels were normal. All except patient D underwent hysterectomy with bilateral salpingo-oophorectomy for severe progressive hirsutism and virilization that did not respond to ovarian suppression with birth-control pills. A wedge biopsy of the ovaries was performed in patient D to rule out virilizing ovarian tumor because the testosterone levels were in the tumor range. In all patients, the ovaries were found to be enlarged to two to three times the normal size. Cut section of the ovaries revealed abundant ovarian stroma with few small follicular cysts in the cortex of the ovary. Histologic examination revealed extensive luteinization of the ovarian stroma in patients B, D, and E. Nests of luteinized cells were present in the ovarian stroma of patients A and C.

Binding studies with ovarian stroma. To prepare ovarian microsomal membranes, we used with minor modification a technique developed for cartilage plasma membranes.[9] Ovarian stromal tissue (400 to 500 mg) was homogenized in 15 ml 0.01 mol/L imidazole, 0.25 mol/L sucrose, and 0.005 mol/L ethylenediaminetetraacetic acid (EDTA), pH 7.5 (ISE buffer) at 0° C for 60 seconds at half-speed with a polytron (Brinkman Instruments, Westbury, N.Y.). The homogenate was centrifuged at 1000 *g* for 15 minutes to remove nuclei, most mitochondria, and tissue fragments. The resulting supernatant was centrifuged at 35,000 *g* for 60 minutes to provide a final pellet that was resuspended in 0.001 mol/L imidazol, pH 7.5.

Insulin and insulin-like growth factor I binding studies were performed in 0.1 mol/L HEPES acid, 0.120 mol/L sodium chloride, 0.0012 mol/L magnesium sulfate, 0.001 mol/L EDTA, 0.01 mol/L glucose, 0.015 mol/L sodium acetate, and 1% bovine serum albumin, pH 8.0, as previously described.[10] Studies designed for Scatchard analysis of binding parameters consisted of eight different concentrations of insulin performed in triplicate. The concentration of insulin tagged with iodine 125 was approximately 0.05×10^{-9} mol/L. Unlabeled porcine insulin was added to achieve concentrations of 0, 0.2, 0.5, 1, 2, 10, 20, and 1000×10^{-9} mol/L and the membrane protein concentration was ≤1 mg/ml. For insulin-like growth factor I binding studies, unlabeled insulin-like growth factor I and [^{125}I]insulin-like growth factor I were used in similar concentrations. The mixtures were incubated at 4° C for 15 to 18 hours and the membranes were sedimented by centrifugation at 18,000 *g* for 15 minutes and washed once in binding buffer. The results were expressed as the percentage of total radioactivity bound per 100 μg membrane protein. Protein was quantitated

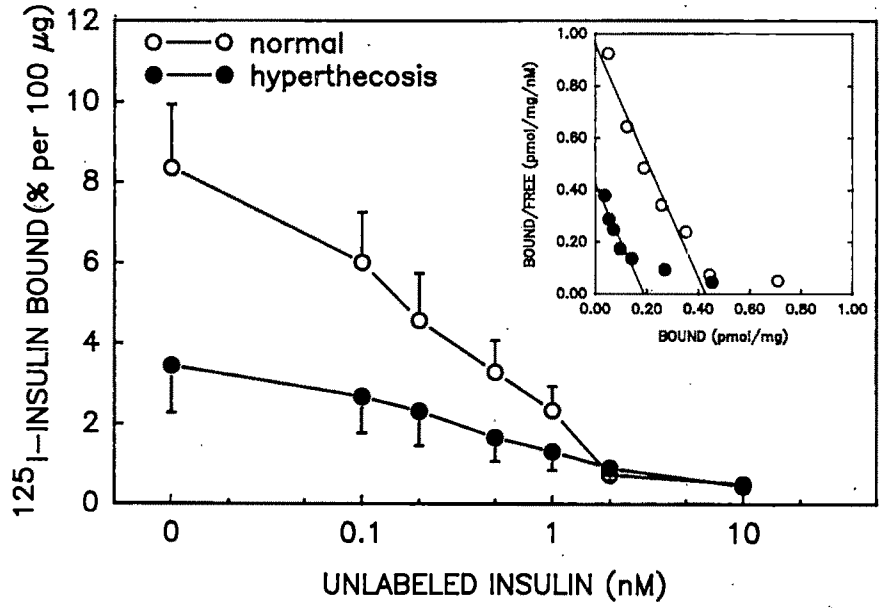

Fig. 1. Mean (±SE) specific insulin binding to ovarian stromal membranes from seven premenopausal women and five women with ovarian hyperthecosis. *Inset* shows Scatchard plot of same data.

by the method of Lowry et al.[11] Nonspecific binding was determined in the presence of at least 200-fold molar excess of unlabeled insulin and insulin-like growth factor I, respectively. Analysis of binding data was performed with a computer program designed to provide the best fit of a two-receptor model to the Scatchard plot. The program performs an iterative curve-stripping procedure in which a curvilinear Scatchard plot is recalculated stepwise, subtracting an increasing number of counts due to low-affinity specific binding until the optimal high-affinity straight line is achieved.[12] The independent Student t test was used to compare differences in specific binding between control women and women with hyperthecosis. A p value < 0.05 was considered significant.

Specificity studies. To evaluate the specificity of insulin-like growth factor I binding, ovarian stromal membranes were incubated in the presence of a constant amount of (1×10^5 counts per minute) of [^{125}I]insulin-like growth factor I, with or without increasing concentrations of unlabeled (1 to 100 ng/tube) insulin-like growth factor I or insulin (1 to 1000 ng/ml).

Results

Insulin binding studies. Our results indicate the presence of specific binding sites for insulin in normal ovarian stromal tissue. The percentage of total insulin binding in normal stroma was 8.3% ± 1.6% (±SE) per 100 μg protein and ranged from 4.3% to 15.2% per 100 μg protein. In women with hyperthecosis, the percent binding of [^{125}I]insulin (3.4% ± 1.1% ±SE) per 100 μg protein; range, 0% to 6.7% per 100 μg protein) was significantly lower ($p < 0.04$) than that observed in normal premenopausal women. The ovarian stroma of patient D did not have any specific binding sites for insulin. Fig. 1 shows the competition curves for binding of [^{125}I]insulin to ovarian stromal membranes of normal premenopausal women and women with hyperthecosis. The inset of Fig. 1 shows the mean data for Scatchard plots. The Scatchard plots were curvilinear, indicating either two binding sites of differing affinity or "negative cooperativity." The Scatchard plots of the high-affinity segments of the data (first five points) were parallel, indicating that the difference in insulin binding was a result of a difference in the concentration of the receptors rather than differences in affinity. The affinity constants for the specific high-affinity insulin receptors from these preparations were similar ($3.5 \pm 1.0 \times 10^9$ L/mol; normal ovarian stroma; and $3.5 \pm 0.8 \times 10^9$ L/mol/ hyperthecosis). The mean receptor concentration in the ovarian stroma of women with hyperthecosis (0.16 ± 0.07 pmol/mg membrane protein) was lower than that in the normal ovarian stroma (0.48 ± 0.18 pmol/mg membrane protein).

Insulin-like growth factor I binding studies. Specific binding sites for insulin-like growth factor I were present in the ovarian stroma from normal premenopausal women. The percentage of total binding of insulin-like growth factor I to normal ovarian stroma was 4.5% ± 1.7% per 100 μg protein (range, 2.0% to 7.4%/100 μg protein). The percentage of total binding insulin-like growth factor I in the ovarian stroma of women with hyperthecosis (7.1% ± 1.7% per 100 μg

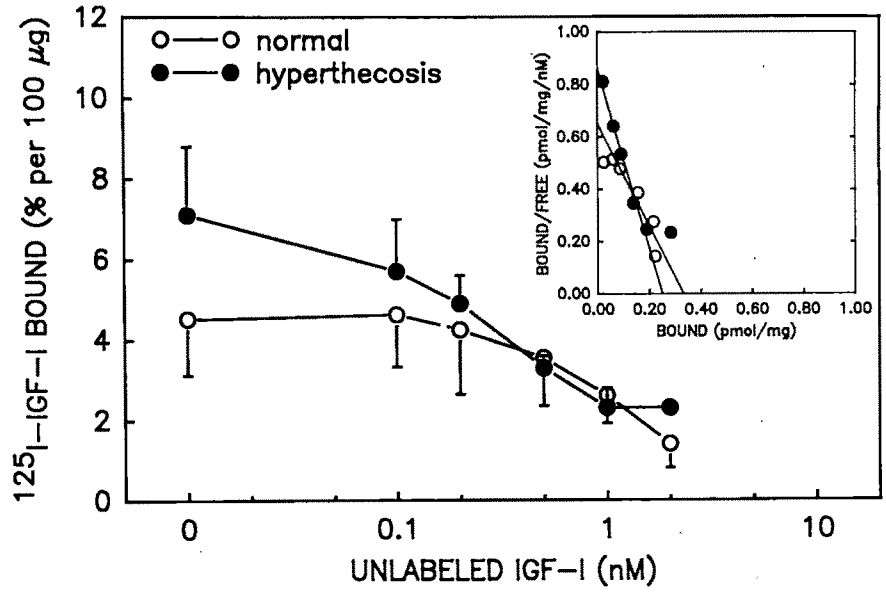

Fig. 2. Mean (± SE) specific insulin-like growth factor I *(IGF-I)* binding to ovarian stromal membranes from premenopausal women and women with hyperthecosis. *Inset* shows Scatchard plot of same data.

protein) was higher than that observed in normal ovarian stroma, but the difference was not statistically significant (Fig. 2). Specific binding sites for insulin-like growth factor I were present in all the ovaries with hyperthecosis (range, 4.1% to 12.7% per 100 μg protein). In patient D, the ovarian stroma did have binding sites for insulin-like growth factor I, even though there was no demonstrable insulin binding. The inset of Fig. 2 shows the mean data from Scatchard plots. The affinity constants for these insulin-like growth factor I receptors were 3.6 ± 1.5 × 10^9 L/mol in hyperthecosis and 1.2 ± 0.3 × 10^9 L/mol in the normal ovarian stroma. The difference was not statistically significant.

Specificity studies. Fig. 3 shows the competition curves for binding of [^{125}I]insulin-like growth factor I to ovarian stromal membranes prepared from normal ovarian stroma and women with hyperthescosis in the absence and presence of varying concentrations of unlabeled insulin-like growth factor I, insulin-like growth factor II, and insulin. Increasing concentrations (1 to 100 nmol/L) of unlabled insulin-like growth factor I resulted in dose-dependent saturable displacement of specific insulin-like growth factor I binding. Insulin was nonreactive at the final concentration of 1000 nmol/L and insulin-like growth factor II was only weakly effective. Results of our specificity studies indicate that human ovarian stromal cells possess separate receptors for insulin and insulin-like growth factor I.

Comment

Specific binding sites for insulin have been shown in the ovarian stroma of normal and polycystic ovaries.[13, 14] However, we are not aware of any previous reports that compare the receptor concentrations in the normal and polycystic ovaries. Our present data indicate that the specific binding sites for insulin are significantly decreased in the ovarian stroma of women with hyperthecosis. Lack of a difference in receptor affinity, as shown by the Scatchard plots, indicates that the reduced [^{125}I]insulin binding is primarily due to a reduction in the number of receptors. This decrease in insulin receptor concentrations could be a result of either a primary receptor defect or a down regulation in response to elevated insulin levels. Poretskey et al.[15] observed a 40% decrease in insulin binding in ovarian tissue when the concentration of insulin in the preincubation medium was 10 ng/ml and complete obliteration of [^{125}I]insulin binding when the concentration was >50 ng/ml. Maximal plasma insulin concentration of 300 to 1000 μU/ml that we observed in our patients after oral glucose ingestion is similar to the dosages used in this study (50 ng/ml ~ 1250 μU/ml).

In the present study, all our patients with hyperthecosis had hyperinsulinemia with normal glucose levels, a finding that indicates insulin resistance and defective insulin action on carbohydrate metabolism. The ability of insulin to alter ovarian function in the face of insulin resistance could be due to point mutations in the insulin receptor that lead to an inability of the insulin receptor to modulate glucose metabolism but do not affect the ability of insulin to bind to the receptor and modulate other functions such as steroidogenesis. The action of hyperinsulinemia on ovarian androgen production may be a result of direct effects of insulin on its own

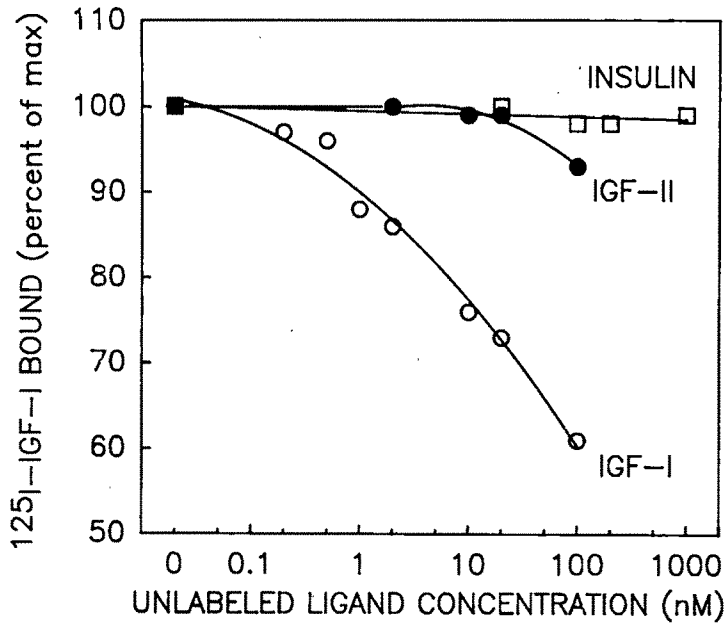

Fig. 3. Specificity of insulin-like growth factor I *(IGF-I)* binding to ovarian stromal membranes.

receptor or cross-over stimulation via the insulin-like growth factor I receptor. Our specificity data shown in Fig. 3 do not support crossover action in this subject because insulin concentrations as high as 1000 nmol/L did not displace [^{125}I]insulin-like growth factor I. However, in many tissues the relative potency of insulin in the prevention of binding of insulin-like growth factor I is 1/50 to 1/200, suggesting that hyperinsulinemia could result in activation of the insulin-like growth factor I receptor.[8] This supposition is further supported by the fact that patients with type B severe insulin resistance, who have antibodies to insulin receptors, have ovarian hyperandrogenism.[16]

Insulin-like growth factor I receptors have previously been shown to be present in the rat interstitial and granulosa cells and swine granulosa cells.[17-19] Specific binding sites for insulin-like growth factor I have also been shown to be present on human granulosa cells.[20] We showed for the first time that there are insulin-like growth factor I receptors in the normal human ovarian stroma. Unlike insulin receptors, the mean receptor concentration of insulin-like growth factor I in ovarian stroma of women with hyperthecosis was higher than that in normal ovarian stroma, even though the difference did not achieve statistical significance. It has been shown in the rat that experimetnal hyperinsulinemia upregulates ovarian insulin-like growth factor I receptors.[21] Small differences in the receptor concentration between the stroma from normal ovary and that from the polycystic ovary could also be a result of the differences in the cell type. Studies by Erikson et al.[22] indicate that the ovarian stromal tissue is heterogeneous and contains primary interstitial cells that have little or no capacity to synthesize steroids and secondary interstitial cells that secrete androgens. In the ovarian stroma of polycystic ovaries, there is a marked increase in the number of steroidogenically active secondary interstitial cells. It is possible that these secondary interstitial cells have an increased number of binding sites for insulin-like growth factor I and the stimulation of androgen synthesis by insulin is mediated through insulin-like growth factor I receptors. The only previous attempt to identify insulin-like growth factor I receptors in the human ovarian stroma is that of Poretsky and colleagues.[14] In that study, minced ovarian tissue rather than stromal membrane preparation was incubated with [^{125}I]insulin-like growth factor I, and the failure to identify insulin-like growth factor I receptors could be because of the difference in methods. After modification of the assay conditions, these authors were able to show specific, high-affinity insulin-like growth factor I binding sites on human granulosa cells.[20]

Inasmuch as the human ovary has both insulin-like growth factor I and insulin receptors, insulin could mediate its action on ovarian steroidogenesis either through its own receptor or through insulin-like growth factor I receptors. In the normal ovary under physiologic conditions, insulin may exert its effect mainly through its own receptors, whereas in polycystic ovarian disease and hyperthecosis, when the insulin receptors may be defective and insulin is present in pharmacologic concentrations, insulin might mediate its action through insulin-like growth factor I receptors. This is further supported by the fact that the ovarian

stroma of patient D, who had severe hyperinsulinemia and ovarian hyperandrogenism, had no measurable insulin receptors.

In conclusion, our present data indicate that (1) the ovarian stroma has specific binding sites both for insulin and for insulin-like growth factor I; (2) in women with hyperthecosis, the ovarian stroma has decreased binding sites for insulin, but has normal or increased concentration of insulin-like growth factor I receptors; and (3) in women with hyperthecosis and hyperinsulinemia, stimulation of ovarian androgen synthesis by insulin may be mediated through the insulin-like growth factor I receptors.

Evidence of heterogeneous mechanisms in lipoprotein lipid alterations in hyperandrogenic women

Robert A. Wild, MD,[a] Mary Bartholomew, MS,[b] Deborah Applebaum-Bowden, PhD,[c] Laurence M. Demers, PhD,[d,e] William Hazzard, MD,[c] and Richard J. Santen, MD[d]

Oklahoma City, Oklahoma, Hershey, Pennsylvania, and Winston-Salem, North Carolina

Fifty-one hyperandrogenic women had their lipoprotein lipid profiles determined. Free and albumin-bound testosterone was associated with triglycerides and with high-density lipoprotein cholesterol independent of fasting insulin levels, percent ideal body weight, and waist/hip ratio. To gain insight into mechanisms of these lipid alterations, the women were subgrouped according to apparent source of androgen excess. Whereas all groups had low levels of high-density lipoprotein-2 cholesterol and high triglyceride concentrations, only in those with high luteinizing hormone–to–follicle-stimulating hormone ratios was free and albumin-bound testosterone associated with triglycerides and high-density lipoprotein cholesterol independent of fasting insulin levels. Relationships between percent ideal body weight and waist/hip ratios, free and albumin-bound testosterone, sex hormone binding globulin, fasting insulin and 2-hour insulin levels and blood pressure are not significant in all subgroups, suggesting differing endocrinological influences and differing mechanisms for lipoprotein lipid alterations. (AM J OBSTET GYNECOL 1990;163:1998-2005.)

Key words: Hyperandrogenism, lipoprotein lipids, polycystic ovaries, hirsutism, coronary vascular disease

We previously found that women with polycystic ovary syndrome have higher triglyceride levels and lower values of high-density lipoprotein (HDL) cholesterol concentrations than those of regularly menstruating nonhirsute, nonhyperandrogenic women.[1] These alterations are apparent when women with polycystic ovary syndrome are compared with normal women matched for body weight.[2] We found that in a separate group of hirsute hyperandrogenic women these lipoprotein lipid alterations are independently associated with elevated levels of insulin and androgen.[3]

There are a number of altered endocrinological influences in hirsute women that can impact on lipid metabolism. Because hirsute women are heterogeneous with respect to sources of androgen excess, we subgrouped our patients according to apparent source of androgen excess to gain insight into possible mechanisms for these lipoprotein lipid alterations.

Material and methods

Fifty-one women with hirsutism were evaluated by history, physical examination, determination of androgens, estrogens, gonadotropins, and fasting and 2-hour postprandial glucose and insulin concentrations. Patients were sampled in the proliferative nonperiovulatory phase of their cycles. Assays were performed in the Core Endocrine Laboratory of the Hershey Medical Center by well-established previously reported procedures.[3] Lipoprotein lipids were determined in the Lipid Laboratory, Department of Medicine, Bowman Gray School of Medicine.[3] All assays were standardized in accordance with the Center for Disease Control. Fourteen-hour fasting lipoprotein lipid profiles were obtained from persons known not to have consumed alcohol for 3 days before sampling. A portion of these results have been reported previously.[3]

Patients with Cushing syndrome, androgen-secreting tumors, or prolactinomas were excluded. All women were in excellent general health. For 3 months before the study, none had taken any medications known to affect pituitary-gonadal function, blood pressure, carbohydrate or lipid metabolism. None had blood pressure >140 mm Hg systolic or 90 mm Hg diastolic. Two women were smokers (5 half pack years and 13 one-pack years) and two were prior smokers (5 years before, but less than a half pack per day for 3 years in their lifetimes). None consumed excessive amounts of alcohol, and none was vegetarian or eating any other special diet. Dietary history, exercise frequency, menstrual history, and family history of cardiovascular disease were

recorded and scored for each patient as described previously.[1]

Corticotropin-stimulation studies to test for adult-onset congenital adrenal hyperplasia were not performed because of the infrequence of its occurrence outside of high-risk populations.[4] None of the women had a clinical history that suggested congenital adrenal hyperplasia (i.e., signs of virilization, early onset of symptoms, short stature, appropriate family history, or Ashkenazi Jewish or Eskimo ancestry.

All women had documented hyperandrogenism. To gain insight into pathophysiologic mechanisms responsible for lipoprotein lipid alterations the women were evaluated and subgrouped according to apparent source of androgen excess. Classic polycystic ovary syndrome includes luteinizing hormone (LH)/follicle-stimulating hormone (FSH) ratio >1.5 and elevations of one or more androgens, free and albumin-bound testosterone, androstenedione, or dehydroepiandrosterone sulfate (DHEAS). Idiopathic ovarian hyperandrogenism includes women with LH/FSH ratio <1.5 and no elevation of DHEAS level. Idiopathic adrenal hyperandrogenism includes persons with elevated DHEAS levels with LH/FSH ratio <1.5 with or without elevated androstenedione concentrations. High-density lipoprotein-2 (HDL_2) cholesterol measurements were obtained in nine patients with polycystic ovary syndrome, in 12 patients with idiopathic ovarian hyperandrogenism, and in four patients with idiopathic adrenal hyperandrogenism. Pearson correlations were made between the lipoprotein lipid parameters, the androgen, insulin, and blood pressure parameters, percent ideal body weight, and waist/hip ratios in each subgroup. Analysis of variance was used to compare mean concentrations of parameters of interest in the three subgroups and to test for differences in mean levels of lipids, androgens, and insulin variables according to waist/hip categories <0.75, >0.75, <0.85, and >0.85 for the entire group of hyperandrogenic women.[5] For the entire group, partial correlation analysis was used to determine independent association of free and albumin-bound testosterone and sex hormone binding globulin with HDL cholesterol and triglycerides independent of fasting insulin levels, percent ideal body weight, and waist/hip ratio. The associations of fasting insulin and 2-hour insulin values with HDL cholesterol and triglycerides independent of free and albumin-bound testosterone, percent ideal body weight, and waist/hip ratio were also described by partial correlation analysis. Partial correlation was also used to determine independent associations of free and albumin-bound testosterone with triglycerides and with HDL cholesterol independent of fasting insulin and 2-hour insulin levels in the women with polycystic ovary syndrome. Log transformations of triglyceride and insulin concentrations were made before analysis.

Results

The correlations and partial correlation coefficients between HDL cholesterol and triglycerides and free and albumin-bound testosterone and sex hormone binding globulin for the entire group of hirsute women are shown in Table I. After adjustment for potential interactions, we found significant associations suggesting that androgen has an influence on lipoprotein lipid profiles independent of insulin levels, percent ideal body weight, and waist/hip ratios.

In contrast, the converse associations of fasting insulin and 2-hour insulin levels (complete data set not shown) with triglycerides ($r = 0.52, p < 0.01$) and HDL cholesterol ($r = -0.39, p < 0.01$) differed when corrected for free and albumin-bound testosterone, percent ideal body weight, and waist/hip ratio. Triglycerides were associated with fasting insulin and 2-hour

insulin levels ($r = 0.37$, and $r = 0.54$, respectively, $p < 0.01$) after correcting for potential interactions with free and albumin-bound testosterone, percent ideal body weight, and waist/hip ratio. However, the associations of HDL cholesterol and fasting insulin and 2-hour insulin levels became nonsignificant when corrections were made for potential interactions.

For the entire group, persons with waist/hip ratios >0.85 had higher fasting and 2-hour postprandial insulin concentrations than those with waist/hip ratios <0.85. Concentrations of sex hormone binding globulin were higher in women with waist/hip ratios <0.75 ($p < 0.05$).

The data suggest that androgen may have more of an effect on HDL cholesterol concentrations and insulin may alter triglyceride metabolism. However, both androgens and insulin may alter lipoprotein lipid metabolism in hirsute women.

The androgen, lipoprotein lipid, and insulin parameters, along with mean ages, weights, and percent ideal body weight for the subgroups of women with hyperandrogenism are shown in Table II. Significant differences among average levels in the three groups were not seen except in LH/FSH ratios, testosterone concentrations, and DHEAS concentrations. Average values for weight, percent ideal body weight, waist/hip ratio, systolic or diastolic blood pressure were not different. The women with idiopathic adrenal hyperandrogenism were heavier but not statistically so. Other potential confounding variables as they related to the three subgroups of the hyperandrogenic women are shown in Table III. None was identified as being significant.

In women with either idiopathic ovarian or idiopathic adrenal hyperandrogenism, no association of any of the lipoprotein lipids was found with any of the androgens or the insulin parameters. The small numbers of patients in the group with idiopathic adrenal hyperandrogenism prevent definitive conclusions; however, all groups were found to have elevated triglyceride levels and all groups were found to have low concentrations of HDL cholesterol. Evidence of insulin resistance was

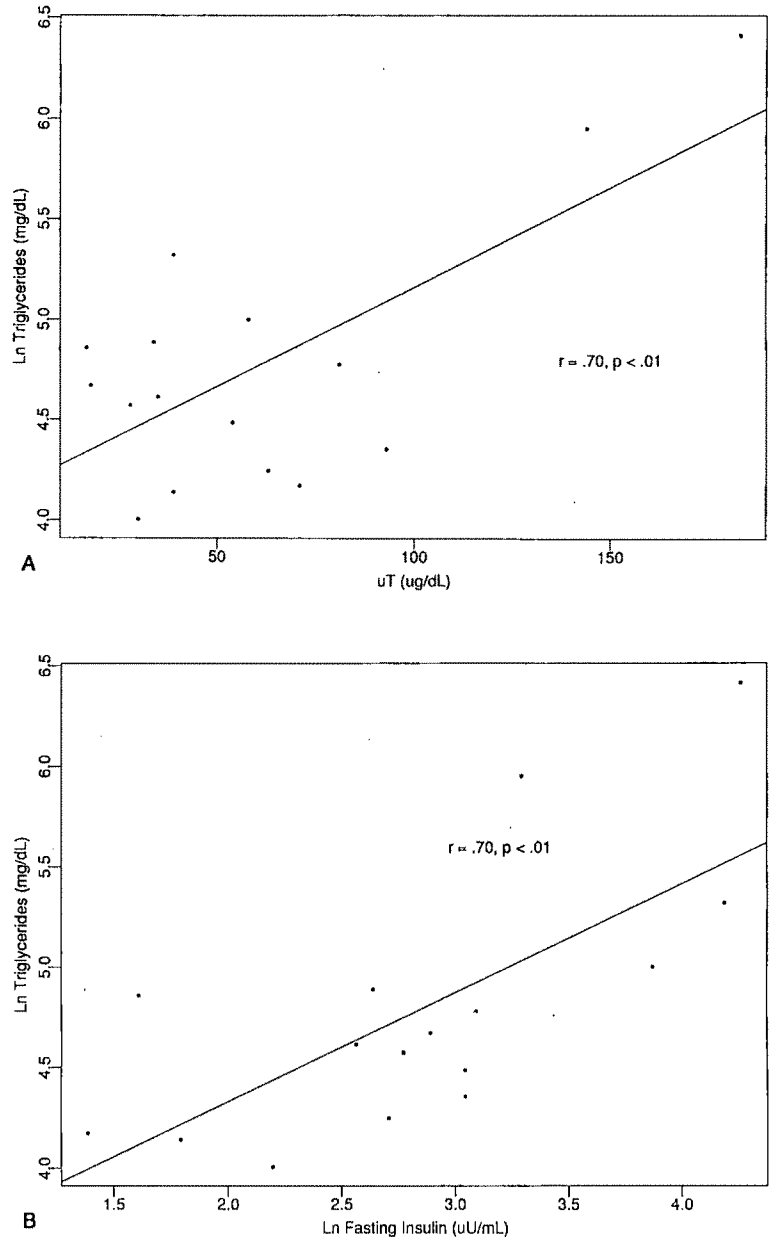

Fig. 1. Association of triglycerides with free and albumin-bound testosterone *(uT)*, **A,** and fasting insulin, **B,** in women with polycystic ovary syndrome.

found in polycystic ovary syndrome and idiopathic adrenal hyperandrogenism subgroups as well, as noted by abnormal high fasting insulin and 2-hour insulin concentrations. All groups had low levels of HDL_2 cholesterol.

Only in women with polycystic ovary syndrome were both free and albumin-bound testosterone (Figs. 1, *A* and 2, *A*) and fasting insulin (Figs. 1, *B* and 2, *B*) associated with triglycerides and negatively with HDL cholesterol (Fig. 2). Note that after adjustment for the effect of insulin, free and albumin-bound testosterone is significantly associated with triglyceride (Fig. 3, *A*) and HDL cholesterol concentrations in these women (Fig. 3, *B*). Fasting insulin level was not associated with HDL cholesterol independent of the effect of free and albumin-bound testosterone.

Tables III and IV show the association of percent ideal body weight and waist/hip ratios to the parameters of interest for the entire group and for the three different subsets.

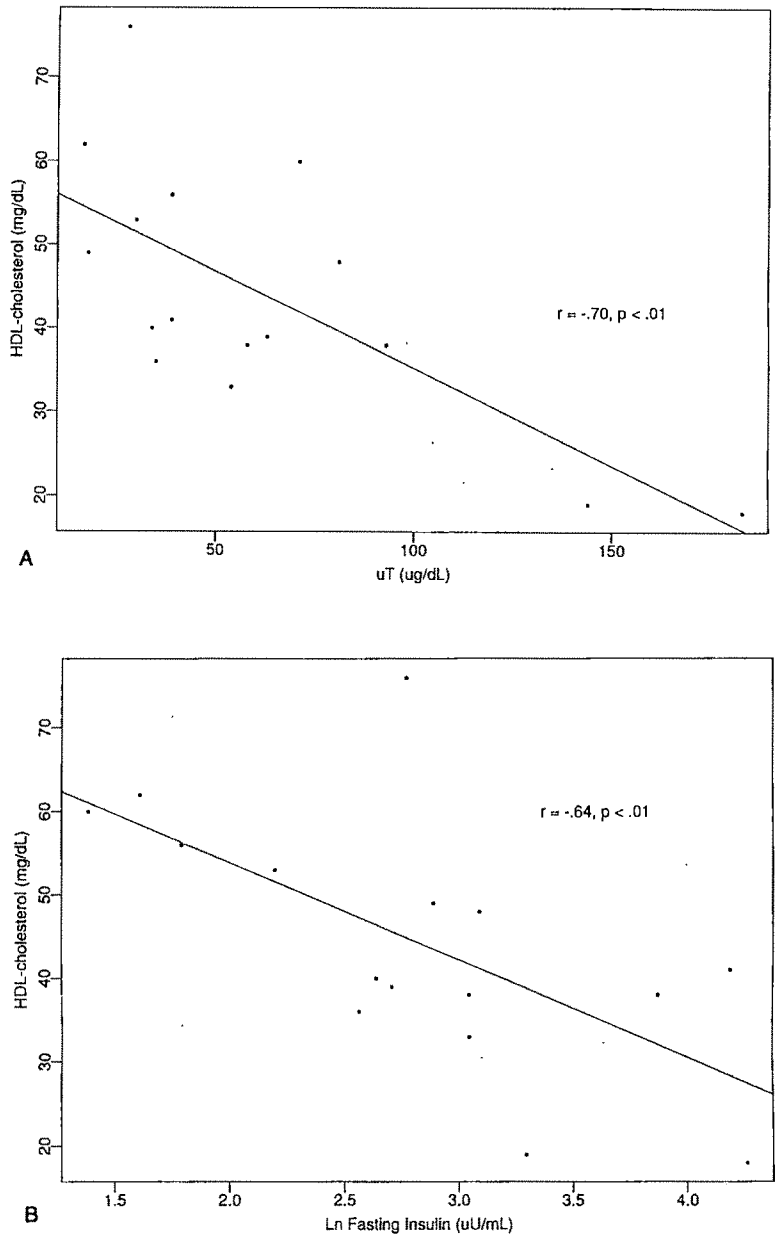

Fig. 2. Association of HDL cholesterol with free and albumin-bound testosterone *(uT)*, **A,** and fasting insulin, **B,** in women with polycystic ovary syndrome.

The associations of free and albumin-bound testosterone and HDL cholesterol were significant for the entire group but not for idiopathic ovarian hyperandrogenism and idiopathic adrenal hyperandrogenism. The strength of the association of free and albumin-bound testosterone with triglycerides and HDL cholesterol in the entire group is therefore carried by the associations found in women with high LH/FSH ratios, depicted here as those with polycystic ovary syndrome.

Comment

Women with hyperandrogenism are heterogeneous with respect to sources of androgen excess. With the exception of a few well-defined inherited disorders[6] any classification of them is arbitrary because there is no uniform agreement as to what constitutes essential criteria for classification. Because LH stimulates ovarian androgen production we have classified our women with androgen excess into those with polycystic ovary syndrome, those with idiopathic ovarian hyperandrogenism, and those with idiopathic adrenal hyperandrogenism to gain insight into possible mechanisms for their demonstrated lipoprotein lipid alterations. Whereas LH is pulsatile, and whereas its pulsatility makes a large difference for any given patient or for small numbers of patients, with pooled group data this

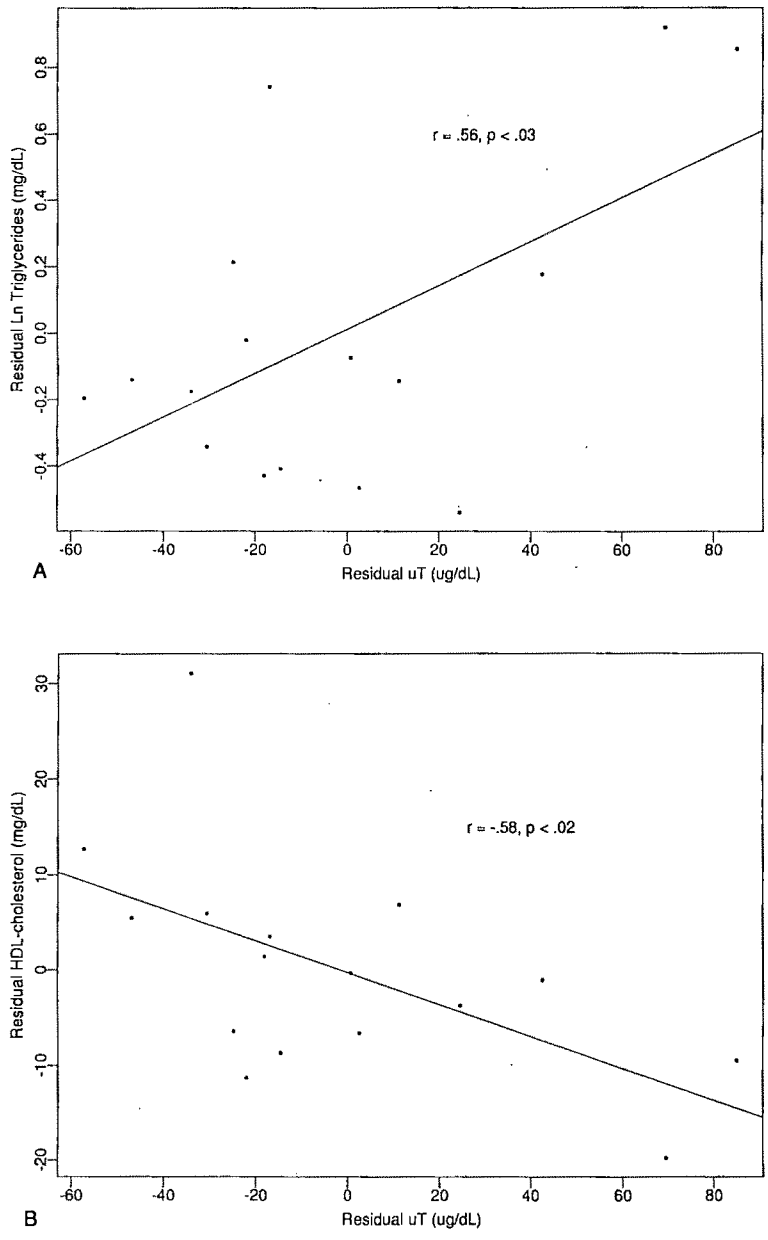

Fig. 3. Association of triglycerides **A**, and HDL cholesterol, **B**, with free and albumin-bound testosterone *(uT)* independent of insulin in women with polycystic ovary syndrome.

makes little difference.[7] It is recognized that the terms *polycystic ovary syndrome, idiopathic adrenal hyperandrogenism,* and *idiopathic ovarian hyperandrogenism* are arbitrary because of potential mixed sources of hyperandrogenism. Even though all women had low HDL and HDL_2 cholesterol levels and elevated triglyceride levels, only those women with high LH values were found to have the previously described associations of free and albumin-bound testosterone and fasting insulin with triglycerides and HDL cholesterol. As previously found[3] free and albumin-bound testosterone was associated positively with triglycerides and negatively with HDL cholesterol independent of insulin.

It is possible that the well-described insulin resistance[8] and the higher amounts of LH-dependent androgen excess in polycystic ovary syndrome influence lipoprotein lipid metabolism. The role of insulin excess associated with insulin resistance in women with polycystic ovary syndrome has had much recent attention. Insulin may act on the ovary either through its own receptor or through insulin-like growth factor I receptors to contribute to androgen production, which may secondarily affect lipoprotein lipid metabolism in these women. Insulin is known to potentiate the effect of LH on ovarian stromal androgen production.[9] Specific binding sites for insulin-like growth factor I in the ovar-

ian stroma of women with polycystic ovary syndrome and hyperthecosis have been found.[10] A feasible alternative mechanism for the altered lipid findings is that insulin working through insulin-like growth factor I receptor in the ovary may stimulate androgen production and secondarily affect lipid metabolism as opposed to insulin's well-known direct effects on liver metabolism. Low levels of HDL_2-cholesterol concentrations were found in all the subgroups. Concentrations of HDL_2 cholesterol fluctuate depending on modulation of hepatic lipase, which is known to be sex steroid responsive,[11] and the action of lipoprotein lipase, which is known to be insulin responsive.[12]

Excess body weight and android body fat distribution independent of the influence of obesity affect insulin resistance in nonhirsute women.[13] Concentrations of sex hormone binding globulin reflect androgen/estrogen[14] and insulin[15] influence. In women with polycystic ovary syndrome, fasting and 2 hour insulin concentrations were associated with waist/hip ratio and percent ideal body weight. In women with idiopathic ovarian hyperandrogenism, the androgen, insulin, and blood pressure variables were associated with percent ideal body weight and waist/hip ratios (Table IV and V). This is of interest because higher waist/hip ratios may reflect androgen influence.[16, 17] Waist/hip ratio is a useful predictor of diseases of the circulatory system.[18] It is likely that these differing associations in women with polycystic ovary syndrome versus idiopathic ovarian hyperandrogenism reflect differing pathophysiologic mechanisms or alternatively similar pathophysiologic influence viewed at different times during development.

Recent epidemiologic data suggest that hyperinsulinism is the initial abnormality that accounts for the association of ischemic heart disease with glucose intolerance, obesity, and hypertension. Hyperinsulinemia is associated with a higher risk of coronary vascular disease than obesity, glucose intolerance, or even diabetes. Healthy persons with hyperinsulinemia and normal glucose tolerance may have an increase in risk factors for cardiovascular disease as compared with a well-matched group of healthy subjects with normal insulin levels.[19] It is possible that women with idiopathic ovarian hyperandrogenism display the insulin resistance X syndrome referred to by Reaven.[20] With aging and long-standing insulin resistance there is elevated insulin, elevated blood pressure, elevated androgen, elevated triglyceride, and lowered HDL cholesterol levels. It is possible that DHEAS confers protection

against death, cardiovascular disease in particular,[21] through disturbing this relationship. Clearly, the relationships between insulin resistance, blood pressure, and lipoprotein lipid metabolism in various subgroups of hyperandrogenic women need further investigation.

Whereas the exact mechanism(s) as to why these alterations occur remains to be elucidated, our studies suggest that women with hyperandrogenism are at increased risk of coronary vascular disease. The insulin resistance, the increased waist/hip ratios, and the altered lipoprotein lipid metabolism that some of these women display, coupled with sedentary life styles,[1] hypertension,[22] and diets low in fiber and high in saturated fats[1] may place some of them at risk of coronary vascular disease. Hirsutism, a common manifestation of androgen excess may signal that risk.[7]

Lectins and heparin-binding features of human spermatozoa as analyzed by flow cytometry

Jaime M. Vasquez, MD,[a, c] Susan F. Magargee, MS,[b] Elaine Kunze, BA,[b] and Roy H. Hammerstedt, PhD[b]

Madison, Wisconsin, and University Park and Philadelphia, Pennsylvania

Sperm cell surface characteristics may serve as a useful diagnostic feature for the evaluation of seminal samples, but to date no useful analytical method(s) is available for their routine quantitative analysis. Fluorescein isothiocyanate–conjugated lectins, proteins with unique and specific saccharide-binding characteristics, and heparin are potentially useful markers for such an analytical procedure. A protocol is outlined whereby frozen semen is thawed and treated with either fluorescein isothiocyanate–conjugated soybean agglutinin SBA *(Glycine max)*, peanut agglutinin PNA *(Arachis hypogaea)*, and garden pea agglutinin PSA *(Pisum sativum)* lectins or fluorescein isothiocyanate–heparin to assess differences in spermatozoa-bound fluorochrome by flow cytometry. Use of propidium iodide to identify nuclei containing sperm cells within the ejaculate is essential to the method because of the large amount of debris associated with the samples. The precision of the assay is high, with the coefficient of variation for the individual probes being <20%. Analysis of a patient pool of 22 revealed that a range in binding properties is observed and a mode of grouping these samples into classes for later analysis is outlined. Semen parameters and fluorescein isothiocyanate–ligand binding values were different in a population of unproven fertility as compared with a comparable population of known fertility. A positive correlation ($p < 0.001$) for garden pea agglutinin PSA binding and concentration of motile cells, percentage of motility, and number of motile cells was found. These data suggest the possible utility of flow cytometry for the assessment of human seminal samples. (Am J Obstet Gynecol 1990;163:2006-12.)

Key words: Lectins, heparin, human spermatozoa, flow cytometry

An elusive goal of andrology research has been the development of laboratory-based assays that possess a predictive capacity for evaluation of the fertility of semen samples; to date no such method(s) has been developed. Reasons are not apparent but may be related to a necessity for a multivariate analysis, with each aspect directed to the evaluation of a unique and obligatory aspect of the functional sperm cell. Reasonable candidates include anlaysis of motility, acrosomal status, and sperm surface features related to sperm binding to the ovum.[1]

Progress toward such a pattern of analysis is being made in that reasonable candidates for sperm functionality have been identified and some quantitative assays have been developed.[1-4] Techniques and instruments for computer-assisted analysis of spermatozoal motility are available, although appropriate incubation and sample preparation techniques for retention (or induction) of motility characteristics appropriate for predictive analysis have yet to be identified. Even less progress has been made in the quantitation of sperm surface characteristics related to successful sperm-ovum binding and acrosomal activation.

Fluorescein isothiocyanate–lectins, high molecular weight glycoproteins with an affinity for saccharide molecules, have been used in conjunction with flow cytometry as probes for terminal saccharides on the surface membranes of ram sperm.[5] Heparin, another glycoprotein whose binding to bull sperm has been tested for correlation to fertility, also may serve as a potential ligand for classification of human spermatozoal surface features.[1, 6, 7]

We describe herein an attempt to classify human sperm by quantitation of binding properties of individual cells by flow cytometry. Because a quantitative evaluation of fertilization potential of human sperm samples is difficult, attention in preliminary studies is best directed to screening samples for those descriptors that reflect extremes in the population. The underlying

assumption of this approach is that a validated quantitative analysis of semen samples from an unscreened (i.e., unknown fertility) population should allow grouping of the population into two or three classes related to the detection of outliers from the population mean. Subsequent studies then can focus on a more refined set of descriptors in a detailed comparison of spermatozoal features and measurements of fertility.

Material and methods

After obtaining the appropriate Human Subject's Committee clearance, semen was collected from 22 males who requested infertility evaluation and one control. The semen was allowed to liquify and was subjected to computer analysis. The control subject was a donor for the artificial insemination program and his fertility had been documented. The control subject provided eight semen samples for flow cytometric analyses at regular intervals throughout the study period. These semen samples were collected and analyzed in parallel with the infertility population. Aliquots were then removed and frozen at −196° C. Frozen sperm samples were rapidly thawed in the presence of 70% ethanol (added 1:1, vol:vol), centrifuged at 300 *g* for 10 minutes, and resuspended in Hanks' balanced salt solution, pH 7.2, buffered with 5 mmol/L HEPES buffer. Cells were diluted to a concentration of 4×10^7 cells/ml.

Computer-assisted semen analysis. Sperm concentrations were evaluated with a Cellsoft automated semen analyzer (CRYO Resources, Ltd., New York, N.Y.). Other sperm traits analyzed included total cell number, concentration of motile cells, percentage of motility, velocity mean, and linearity mean. Standard equipment (Olympus BH2 microscope, 10× objective, 6.7× photographic eyepiece, MTV-3 video camera adaptor, 10-unit Makler chamber) for operation of an automated semen analyzer was used. The general parameters for the semen analysis were as follows: frames, 20; Hz, 30; minimum sampling for motility, 1; minimum sampling for velocity, 3; maximum for velocity, 200; threshold velocity, 8; threshold gray, 115; Pixel scale, 0.688; dilution factor, 1; cell size range, 5 to 25. After computer analysis, aliquots were removed and frozen in 7.5% glycerol at −196° C or without glycerol.

Lectins and heparin. Fluorescein isothiocyanate–conjugated lectins were obtained from E-Y Laboratories (San Mateo, Calif.). The lectins used in this study were as follows: soybean agglutinin SBA *(Glycine max)* (binding specificity for N-acetyl galactosamine residues, and α-D-galactose), peanut agglutinin PNA *(Arachis hypogaea)* (binding specificity for β-D-galactose residues), and garden pea agglutinin PSA *(Pisum sativum)* (binding specificity for α-D-mannose). Fluorescein isothiocyanate–heparin was purchased from Polysciences (Warranton, Pa.). Extensive preliminary experiments (data not presented) established the following protocol. In a final volume of 0.5 ml, 0.05 ml cells (2×10^6) were added to fluorescein isothiocyanate–conjugated lectin (1 to 210 μg), 10 μg propidium iodide and brought to a final volume of 0.5 ml with Hanks' balanced salt solution. Cells were incubated at room temperature for 30 minutes. Preliminary tests indicated that lectin binding was maximum by this time and no further increase in cellular fluorescence was noted when longer incubation times were used.

Automated quantification by flow cytometry. Fluorescence measurements were performed on a flow cytometer EPICS V, (Coulter Electronics, Hialeah, Fla.). The filters were arranged as follows: 515 nm laser blocking filter, 560 dichroic with an additional 515 nm long pass filter in front of the green photomultiplier tube (lectin-fluorescein isothiocyanate measurement) and a 590 long pass in front of the red photomultiplier tube [PI-deoxyribonucleic acid (DNA) measurement]. Photomultiplier high-voltage settings were adjusted so that 10 μm fluorescent microspheres (lot number 4009, Coulter Electronics) fell in channel 172 for the log integrated green fluorescence parameter. The amplifier gains were adjusted to place the maximum signal from these standards in the same channel (172), thus minimizing variability between experiments. The instrument-default set-threshold-gating value for the amplifiers was used during data acquisition. All measurements were gated on log integrated red fluorescence which is a measure of DNA, to eliminate debris and clumps from the lectin distribution. Under these operating conditions, no signal was detected when unstained cells were passed through the instrument. Thus all data displayed represent sperm with varying amounts of bound lectin or heparin. A total of 1×10^4 sperm cells with this gate were counted.

Results

The necessity of counterstaining and gating for propidium iodide-positive cells (DNA-containing) cannot be overemphasized. Typically, only 25% to 40% of each sample were DNA-containing particles. The remainder was debris.

To eliminate potential health hazards associated with semen that contains the frozen sperm human immunodeficiency virus (HIV), suspension was thawed in the presence of equal volume of 70% ethanol. Such treatment could displace glycoproteins from the sperm surface, but the practice was viewed as reasonable because the analysis involves formation of microdroplets during analysis by flow cytometry. In an experiment to compare fresh versus ethanol-treated bovine sperm (data not shown), neither the population distribution nor the total amount of fluorescein isothiocyanate–heparin bound per cell was altered by the ethanol treatment.

Table I. Differences in seminal properties and fluorescein isothiocyanate–conjugated ligand voltages between subjects with unproven fertility and control ejaculates (means ± SEM)

	Unproved fertility	*Control*	*p Value*
Concentration (million/ml)	60.8 ± 8.3	110.3 ± 13.3	0.0001
Concentration of motile cells (million/ml)	38.2 ± 8.3	59.8 ± 16.3	0.018
Motility (%)	50.3 ± 5.2	58.8 ± 6.3	0.12
Total no. cells per ejaculate (millions)	174.6 ± 28.5	231.8 ± 31.3	0.059
Velocity (μm/sec)	39.3 ± 1.9	43.7 ± 2.3	0.039
Linearity	5.2 ± 0.1	5.8 ± 0.2	0.0001
Abnormal morphology (%)	16.4 ± 2.3	19.6 ± 2.6	0.185
White blood cells* (/hpf)	6.4 ± 1.7	6 ± 1.5	0.806
pH	7.4 ± 0.07	7.3 ± 0.05	0.359

PNA	0.113 ± 0.006	0.202 ± 0.007	0.0001
PSA	0.151 ± 0.01	0.335 ± 0.021	0.0001

SBA, Soybean agglutinin SBA; *PNA*, peanut agglutinin PNA; *PSA*, garden pea agglutinin PSA.
*Per high-power field.

A one-sample Student's *t*-test[17] was used to compare the differences in seminal properties and fluorescein isothiocyanate–ligand voltages between the patients with unproved fertility and the ejaculates obtained from the control (Table I). This revealed a significant difference in several semen parameters ($p < 0.05$) and all fluorescein isothiocyanate–ligands used ($p < 0.001$).

Linear regression models were used to compare fluorescein isothiocyanate–ligands bound to sperm and semen characteristics.[17] Data were analyzed with a minimum confidence level of 95%. Analysis of binding of fluorescein isothiocyanate–ligands relative to seminal properties determined by an automated semen analyzer revealed a positive correlation ($p < 0.0001$) for garden pea agglutinin PSA binding and percentage of motility, concentration of motile cells, and number of motile cells. A negative correlation ($p < 0.05$) for garden pea agglutinin PSA and percentage of abnormal cells was also found. The remaining seminal traits of ejaculate volume, sperm velocity, linearity, ejaculate pH, and white blood cell count were not correlated with the binding of any of the fluorescein isothiocyanate–ligands.

Preliminary experiments determined the concentration of lectin or heparin necessary to accurately estimate the surface determinants and thereby allow quantitative comparisons of semen samples. Nonspecific binding of lectins was evaluated (data not shown) by adding sugars that competitively displace the fluorescein isothiocyanate–lectin from the surface. The fluorescence associated with the sperm cells was reduced about tenfold by such treatment. Attempts to accomplish a similar test for heparin were unsuccessful because no true competitive ligand is available to displace any previously bound fluorochrome. The results (Fig. 1) of a titration of fluorescein isothiocyanate–lectin or heparin versus fluorescence intensity as assessed in the flow cytometer established that the following amounts of ligand were sufficient to allow estimation of the binding capacity of the surface of the cells: soybean agglutinin SBA and peanut agglutinin PNA, 70 μg; garden pea agglutinin PSA, 60 μg; and heparin, 100 μg. Tests of other lectins, castor bean agglutinin RCA *(Ricinus communis)* and concanavalin A agglutinin Con A *(Canavalia ensiformis)* established that accurate analyses could not be accomplished at lectin contents of <70 μg; therefore these ligands were not studied further. A typical distribution profile for one subject (assayed with the stated ligand concentrations) for the three lectins and heparin is provided in Fig. 2. An estimate of fluorescence intensity per sample for the 1×10^4 sperm analyzed is indicated by an asterisk. For all subsequent comparisons, this expression of the primary data for peak intensity (expressed as channel number and on a logarithmic scale) was converted to phototube voltage on a linear scale.

Once the appropriate level of lectin or heparin was established, a single semen sample from each of 22 subjects was analyzed. In addition, replicate analyses of eight semen samples obtained from a single subject with proved fertility over a 3-month period were made for comparison with the infertile population and to determine the variability in the assay (Fig. 3); the coefficient of variation for this subject was 4.5% for heparin, 13.9% for soybean agglutinin SBA, 10.1% for peanut agglutinin PNA, and 17.4% for garden pea agglutinin PSA.

To detect outliers in this set of semen samples, the mean fluorescence for each lectin was calculated for the

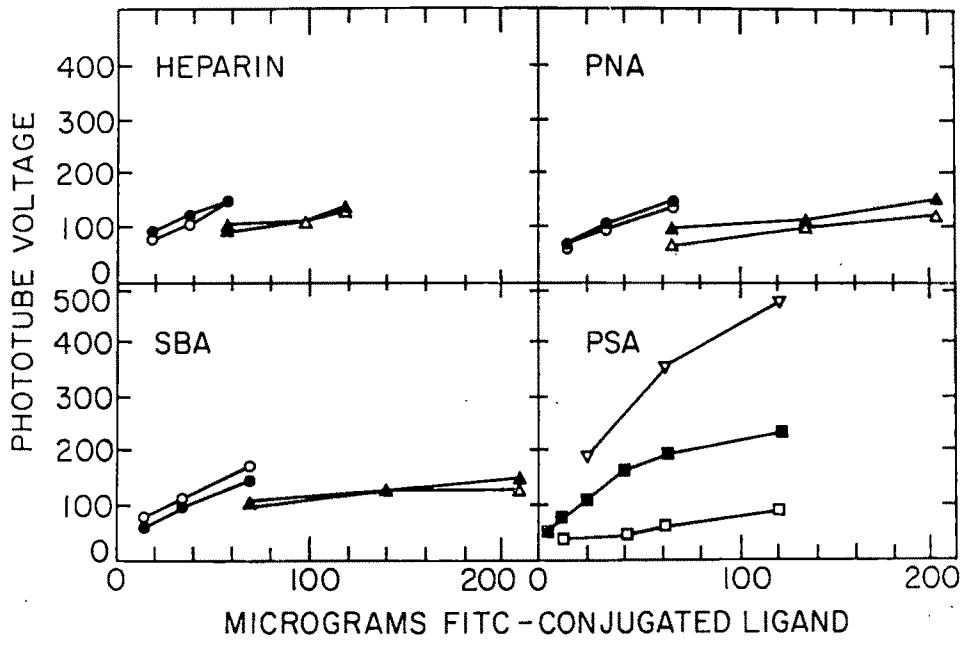

Fig. 1. Titration of sperm surfaces with increasing ligand concentration. Sperm were treated with increasing concentrations of fluorescein isothiocyanate–ligand and fluorescence intensity of nucleated particles in suspension was assessed as outlined in text. These data established that reproducible evaluation of extent of ligand binding to sperm could be accomplished for the four compounds presented. Those curves with identical symbols represent analyses of same sperm suspension with different ligands.

22 singly analyzed samples. The equation $[(X_n - X_{mean})/SD]$ was used to display the difference between the sample value (X_n) and the population mean (X_{mean}) in terms of the SD for that lectin (Fig. 4). For comparison, the control sample with its SD for eight replicate analyses is presented. The 22 samples were grouped into classes (Table II) according to their difference from the sample mean. The scheme used for subsequent comparisons was: group a, within 1 SD of the mean; group b, >1 SD but <2 SD from the mean; and group c, >2 SD from the mean.

An example of a subject with uniquely high binding capacity was subject 22. This subject had normal semen parameters according to our laboratory (concentration, 64.5 million/ml; percentage of motility, 57%; concentration of motile cells, 37.3 million/ml; abnormal forms, 22%).

Comment

The initiation of a study of potentially important descriptors of the sperm surface is critically dependent on the choice of ligand for the study. Our choices were made on the basis of previous results for human and ram sperm. Two ligands have been shown to be related to features known to be involved in successful sperm-ovum binding. Heparin binding to human sperm has been shown to be positively correlated with the capacity of such sperm preparations to bind and penetrate denuded hamster ova[1] whereas garden pea agglutinin PSA binding to human sperm has been shown to be directly related to extent of the acrosome reaction.[8, 9] Thus differences among subjects in these two parameters could be related to fertilization capacity. The other two ligands studied, soybean agglutinin SBA and peanut agglutinin PNA, were chosen because previous studies of ram sperm revealed changes in their binding capacity associated with physiologic states; however, no direct relationship to fertilization capacity has been inferred from previous data.

The large amount of debris (e.g., nonnucleated particles) in human semen presents a special challenge to analysis by flow cytometry. Use of propidium iodide to select (gate on) particles for analysis is critical because some of the debris binds lectins and heparin. As an example, when heparin binding to all particles was analyzed at least three populations of fluorescent particles were detected rather than the single distribution shown in Fig. 2.

In our study, samples from the patients and the control subject were collected throughout the study period but were assayed simultaneously to avoid interassay variation and statistical bias. This required storing frozen samples until the assays were performed. In addition, because of obvious reasons, the use of frozen samples was the only way in which two laboratories from different parts of the country could collaborate in this project.

It is true that the use of frozen-thawed sperm may

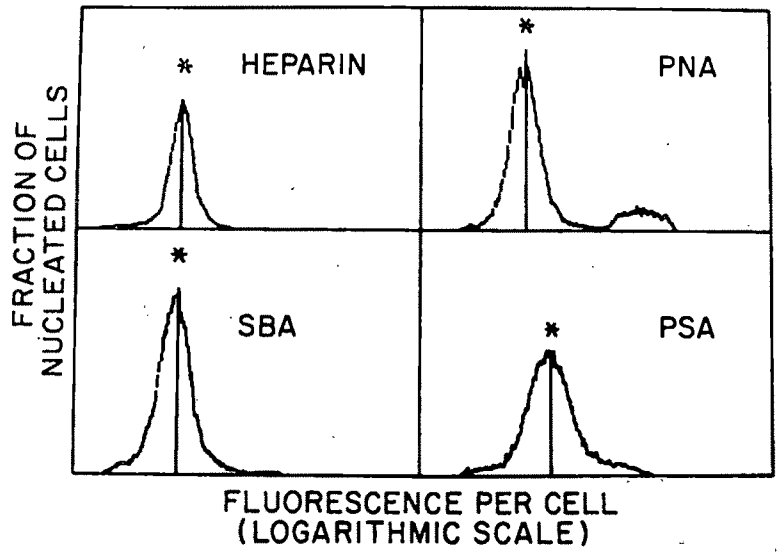

Fig. 2. Binding properties of ligands to sperm within a seminal sample. When sperm were assayed under optimum concentrations of fluorescein isothiocyanate–ligand (see text), homogeneous distribution of amount of fluorescence per cell (logarithmic scale; X axis) versus percent of population with nucleated particles (sperm; linear scale; Y axis) was detected for each ligand. Position of major peak in each distribution on the basis of analysis of 1×10^4 sperm, is marked with *asterisk;* this fluorescence value was used as descriptor for entire population in subsequent calculations.

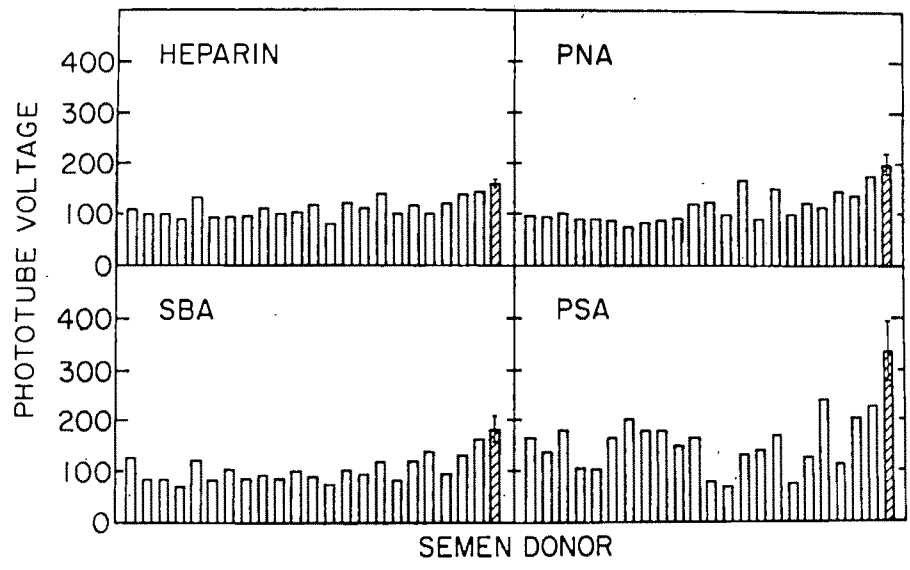

Fig. 3. Analysis of ligand binding properties of individual ejaculates by flow cytometry. Single ejaculates from 22 men were analyzed as outlined in text. Fluorescence intensity of major peak (*asterisk,* Fig. 2) was transformed from channel number (logarithmic scale) to linear scale (voltage) for direct comparison in this plot. *Last bar to right (cross-hatch)* represents mean value (± 1 SD) for analysis of eight ejaculates from one control subject.

lead to the release or exposure of internal components from their membranes. However, the Center for Disease Control and the American Fertility Society have recommended the exclusive use of frozen semen as an important safeguard for patients.[10, 11] Thus it is important to develop techniques to quantitatively assess potential for fertility of cryopreserved human semen samples, although the conclusions drawn from these descriptors may not necessarily apply to fresh spermatozoa.

Although we noted that in fresh versus ethanol-treated bovine spermatozoa there was no difference in the amount of ligand bound per cell or in the population distribution, this experiment could not be carried

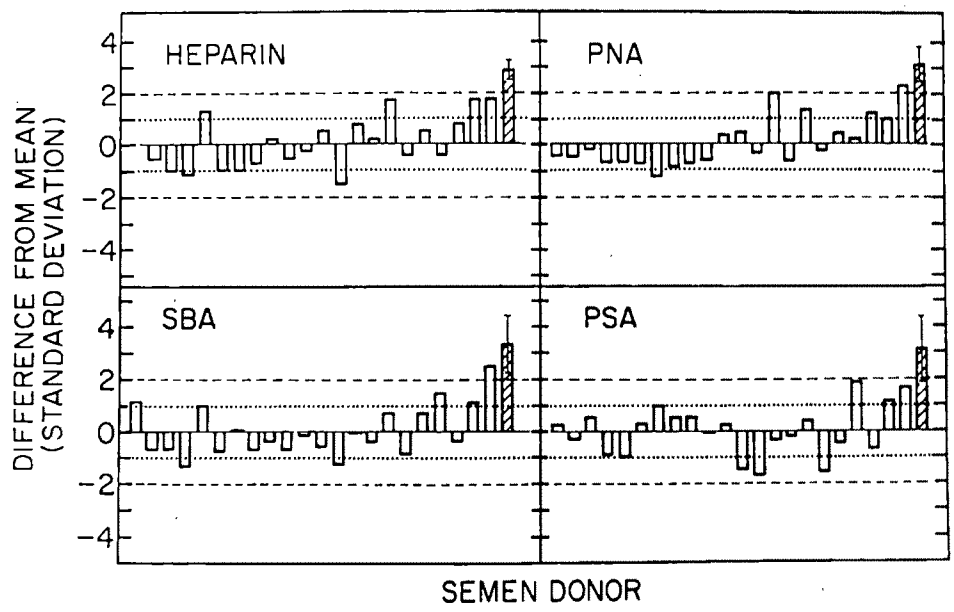

Fig. 4. Normalization of ligand binding properties of individual ejaculates. Data of Fig. 3 were normalized relative to mean binding properties of the 22 samples analyzed. Expression of difference in total binding for each sample from that of mean (in terms of SD for binding of that ligand) allows direct comparison within subjects across ligands to be tested. *Light line* represents ± 1 SD and *heavy line* represents ± 2 SD. Population mean ± SEM (expressed in volts output from detector per cell analyzed) for each lectin were as follows: heparin, 0.110 ± 0.018; soybean agglutinin SBA, 0.102 ± 0.023; peanut agglutinin PNA, 0.113 ± 0.047; garden pea agglutinin PSA, 0.151 ± 0.047. Last bar *(cross-hatch)* represents mean value (± 1 SD) for analysis of eight ejaculates from one subject and was not included in population mean.

out with human spermatozoa. In the past, some investigators performed fluorescence-activated cell sorting of human spermatozoa without ethanol treatment.[13] However, this practice is now considered unsafe because HIV has been isolated from the semen of patients with HIV after the samples were cryopreserved in liquid nitrogen.[14] An experiment comparing fresh versus ethanol-treated human spermatozoa would defy current recommendations from the Center for Disease Control to prevent the formation of HIV-containing microdroplets.[15, 16]

The lectin-binding properties of human sperm are remarkably constant and homogeneous. Under the conditions used, a single major population was detected. For the sample assayed to establish repeatability, the fluorescence intensities of the individual ejaculates were highly reproducible with a coefficient of variation of <20% approaching that expected from standard gamete biology laboratory assays. Such reproducibility should allow detection of those sperm preparations that possess unique binding features.

Sperm preparations with uniquely high or low binding capacities for the ligands tested were detected (Fig. 4 and Table II). Over half the samples analyzed had binding properties within 1 SD of the mean (group a of Table II). Assays with both the ligands with unknown relation to fertilization capacity (soybean agglutinin SBA and peanut agglutinin PNA) and the pair (heparin

SBA, Soybean agglutinin SBA; *PNA*, peanut agglutinin PNA; *PSA*, garden pea agglutinin PSA.

Binding properties of sperm were assessed from the data presented in Fig. 4 and classified according to the scheme presented in the text. A plus or minus sign indicates a value above or below the population mean, respectively.

and garden pea agglutinin PSA) previously related to essential features of sperm-ova interactions, revealed individual samples with uniquely high or low binding capacities. For example, subject 22 had high binding capacity especially for soybean agglutinin SBA and peanut agglutinin PNA, and this subject had normal semen parameters. Also note that in the control subject the binding values for all the probes, including heparin, were >2 SDs from the infertile population mean. At this time the significance of such variation is unknown, but the ability to precisely detect such variants is essential to an eventual test of any relation to fertilization capacity of the sperm preparation.

A statistical test of the ligand-binding variables with results of analysis by an automated semen analyzer of seminal properties before freezing revealed a few relationships: a positive correlation ($p < 0.0001$) for garden pea agglutinin PSA binding and concentration of motile cells, percentage of motility, and number of motile cells. The significance of these is not apparent because no relationship of motility to a surface property has been established. However, a positive correlation between these seminal properties and fertilization of human oocytes in vitro has been shown by other investigators.[12]

Fluorescein isothiocyanate–lectin and fluorescein isothiocyanate–heparin binding has not been related to fertility in human beings. However, the correlations between these fluorescein isothiocyanate–ligands and several sperm physical and morphologic traits suggest the possible use of flow cytometry to assess human semen. In addition, the differences in fluorescein isothiocyanate–ligand measurements between patients and control ejaculates indicate that the binding of these probes may be a predictor of fertility in human beings. Further research is warranted to establish the usefulness of this assay, particularly in a clinical context.

Preembryo biopsy and analysis of blastomeres by in situ hybridization

Jamie A. Grifo, MD, PhD,[a,*] Ann Boyle, BS, MS,[b] Evan Fischer, BA,[a] Gad Lavy, MD,[a] Alan H. DeCherney MD,[a] David C. Ward, PhD,[b] and Mrinal K. Sanyal, PhD[a]

New Haven, Connecticut

We developed a method for the biopsy of preimplantation mouse embryos (preembryos) at the four- to eight-cell stage, which uses partial zona pellucida dissection. The preembryos were collected in calcium- and magnesium-free phosphate-buffered saline solution with 0.01% ethylenediaminetetraacetic acid, 0.1 mol/L sucrose, and 4 mg/ml of bovine serum albumin to facilitate removal of blastomeres. This allows entry of a fine micropipette into the perivitelline cavity with subsequent removal of a single blastomere by gentle suction. The majority of embryos (75%) from which biopsy specimens were obtained in this fashion developed to the blastocyst stage. The blastomeres obtained were mainly intact and they were fixed to glass slides. After permeabilization, in situ hybridization was performed with chromosome X– and chromosome 3–specific probes. Human unfertilized eggs and blastomeres from human polyspermic embryos also have been analyzed by in situ hybridization with chromosome specific probes. The combination of nondestructive embryo biopsy and in situ hybridization is a possible approach for preimplantation genetic diagnosis. (Am J Obstet Gynecol 1990;163:2013-9.)

Key words: Preembryo biopsy, in situ hybridization, blastomere

Recent advances in molecular genetics have improved the sensitivity of methods used for genetic diagnosis. Two techniques in particular, the polymerase chain reaction and in situ hybridization permit the analysis of the genetic material of a single cell. The sensitivity of polymerase chain reaction is achieved by enzymatic amplification of target deoxyribonucleic acid (DNA) sequences by a factor of 10^5-fold or more.[1] In contrast, in situ hybridization allows the direct visualization of single genes in metaphase chromosomes or interphase nuclei.[2,3] The micromanipulation of preembryos could allow specific preimplantation diagnoses to be made. Currently, genetic diagnoses are limited to the postimplantation period and are performed by chorionic villus sampling or amniocentesis. If genetic diagnoses could be achieved in preimplantation embryos with no untoward effects then in vitro fertilization technology could be used for fertile couples at genetic risk. Because a broad range of diseases can be diagnosed by polymerase chain reaction or in situ hybridization, the technique of in vitro fertilization coupled with preembryo biopsy could provide the conduit from which these technologies can be applied to the human species.

Edwards[4] first suggested that sex-linked recessive disorders could be diagnosed by sampling trophoblast cells removed from blastocysts. Sex of bovine preembryos has been determined by chromosome analysis[5,6] or Y chromosome–specific DNA probes.[7] Monk et al.[8] have diagnosed a deficiency of the X-linked enzyme hypoxanthine phosphoribosyl transferase in mouse preembryos before transfer. However, analyses of this nature are limited to enzyme deficiency diseases that can be detected by microenzyme assay. Trophectoderm biopsy has been successfully carried out in marmoset monkey. These cells were cultured for analysis and the embryos were transferred with resultant live-born offspring.[9] Sex of the human preembryo has been successfully determined with chromosome-specific probes and in situ hybridization. However, this used a tritiated Y chromosome–specific probe that required a long time for diagnosis and the analysis used the whole embryo in a destructive fashion.[10] Whereas this method is successful, it would provide no clinical application. Recently, Handyside et al.[11] determined the sex of the human preembryo in a nondestructive fashion with embryo biopsy in conjunction with polymerase chain reaction. They were able to remove a single blastomere, amplify Y-specific DNA repeat sequences, and culture embryos from which biopsy specimens were obtained to blastocysts at the same rate as that of embryos from

which biopsy specimens were not obtained. Holding and Monk[12] diagnosed β-thalassaemia by polymerase chain reaction in single blastomeres from mouse preimplantation embryos. The unique feature of this study is that they were able to amplify a region of a gene in a single diploid blastomere by a method that is theoretically applicable to any single copy genetic disorder in which a mutation or deletion is the cause. Wilton and Trounsen[13] recently described a method of mouse preembryo biopsy with successful cryopreservation. In addition, they developed a method for culture of blastomeres that after 6 days resulted in 20-cell nuclei per cultured blastomere.[14] Whereas in situ hybridization can be applied to a single cell, the ability to culture blastomeres would facilitate a more reliable diagnosis. In situ hybridization allows numeric chromosome analysis and is not limited by contamination. These are distinct advantages over polymerase chain reaction for analysis of single cells.

In this article we describe a method of embryo biopsy that uses partial zona dissection and we describe the first successful in situ hybridization with blastomeres obtained by embryo micromanipulation. In addition, we performed in situ hybridization with both unfertilized human eggs and with polyspermic human embryos.

Material and methods

Embryo collection. Female mice B6xC3/F1 were superovulated by intraperitoneal injections of 5 IU of pregnant mare serum gonadotropin (Gestyl, Diosynth) followed 48 hours later by 5 IU of human chorionic gonadotropin (Pregnyl, Organon) and mated with male B6xC3/F1 mice. Mated females were killed approximately 48 hours later and embryos were flushed from the oviducts with either Hoppe-Pitts media or phosphate-buffered saline solution with 4 mg/ml bovine serum albumin. Embryos were obtained at the two-cell to four-cell stage and 80% to 90% achieved the blastocyst stage when cultured in our system. Four- to eight-cell embryos were incubated for 30 minutes in calcium- and magnesium-free phosphate-buffered saline solution with 0.01% sodium ethylenediaminetetraacetic acid (EDTA) to reduce intercellular contacts. They were transferred to a small drop on a Lab-Tek microculture slide with the plastic chamber removed and covered with paraffin oil equilibrated with phosphate-buffered saline solution. Human polyploid embryos and oocytes that failed to fertilize were obtained from the in vitro fertilization program (Human Investigation Protocol 5443).

Micromanipulation. A single blastomere was removed from four- to eight-cell embryos with an inverted microscope and Narishige micromanipulators (Fig. 1). A holding pipette of approximately 80 μmol/L outside diameter with a 30 μmol/L inside diameter was fire polished with a Nikon microforge. A sharpened dissection pipette was used for zona dissection and a microbiopsy pipette was pulled to a 10 to 20 μmol/L outside diameter with a 5 to 15 μmol/L inside diameter. The preembryo was stabilized with gentle suction through the holding pipette and a slit was made through the zona pellucida with a sharpened dissection pipette similar to the method of Malter and Cohen.[15] The dissection pipette was removed and replaced by a biopsy pipette that was placed into the zona slit, and a blastomere was aspirated partially into the pipette under controlled suction. The blastomere was removed from the zona and the preembryo was placed into the Hoppe-Pitts media for continued culture after three passes into fresh media droplets. Embryo culture was done in microdrops under paraffin oil equilibrated with media.

Analysis of blastomeres. Blastomeres obtained in media droplets under oil were fixed directly onto the tissue culture slides under a Zeiss dissecting microscope in the following fashion. Two fixation protocols were used, one with 4% paraformaldehyde in 1/2X phosphate-buffered saline solution the other with 0.075 mol/L potassium chloride solution to swell the cell. Media was replaced with 4% paraformaldehyde in 1/2X phosphate-buffered saline solution or 0.075 mol/L potassium chloride and blastomeres incubated for 15 to 30 minutes. The oil was removed by suction and the solution surrounding the blastomere was removed without dislodging it. As the blastomeres started to air dry methanol/acetic acid (3:1) was dropped on to further fix them to the slide. This last step was repeated after air drying and finally 100% methanol was applied to remove excess oil and debris. Blastomeres were stored fixed at 4° C. Later experiments showed no need for paraformaldehyde fixation and this step was omitted. When this was done no permeabilization was required either. Human oocytes and polyploid embryos were processed in a manner similar to mouse preembryos; however, polyploid preembryos were not cultured after biopsy because all blastomeres were fixed to glass slides. The polyploid embryo shown in Fig. 2 had five blastomeres in it and only three were retained on the glass slide after the in situ hybridization procedure.

Permeabilization. Blastomeres were equilibrated in phosphate-buffered saline solution with 20% glycerol for 30 minutes and then 0.5% triton (vol/vol), 0.5% saponin (wt/vol) in phosphate-buffered saline solution for 10 minutes. The slides were immersed in liquid nitrogen for 5 seconds and allowed to thaw. Two additional freeze-thaw steps were performed. This permeabilized the cell to allow biotinylated DNA probes access to the nucleus during in situ hybridization. When it was omitted variable results were obtained with in situ hybridization in paraformaldehyde-fixed blas-

Preembryo biopsy with zona dissection and removal of blastomere. **Panel A,** Four-cell mouse preembryo with slit in zona is immobilized on holding pipette. **Panel B,** Biopsy pipette is placed gently inside zona pellucida. **Panel C,** Gentle aspiration is used to remove blastomere from zona pellucida. **Panel D,** Blastomere is completely removed. **Panel E,** Embryo and blastomere are released into media. **Panel F,** Hatching blastocysts obtained from biopsied preembryos from which biopsy specimens were obtained.

tomeres. Later experiments showed that swelling the cells with 0.075 mol/L potassium chloride followed by fixation with acetic acid/methanol (1:3) also achieved adequate permeabilization.

DNA probes. The X repeat probe 60-36, a 4.2 kilobase (kb) insert was kindly provided by Dr. Christine Disteche.[16] It is a 4.2 kb sequence repeated approximately 50 times and maps just below and is not within the centromere. Probe MαG-6, a cosmid containing the genomic sequence for the sodium/potassium adenosine triphosphatase gene was provided by Dr. David Housman. It is a 40 kb insert that hybridizes the α-subunit single-copy gene.[17] The human Y repeat probe hybridizes to pHY2.1, a 2.1 kb sequence that is repeated approximately 2000 times on the long arm of the Y chromosome.[18] Probes were labeled with biotinylated-11-dUTP by nick translation.[2] The probes were nick translated intact with both the vector and insert and used in this form for in situ hybridization.

In situ hybridization. The X repeat probes and MαG-6 probes were used at a concentration of 6 μg/ml, which are standard amounts for in situ hybrid-

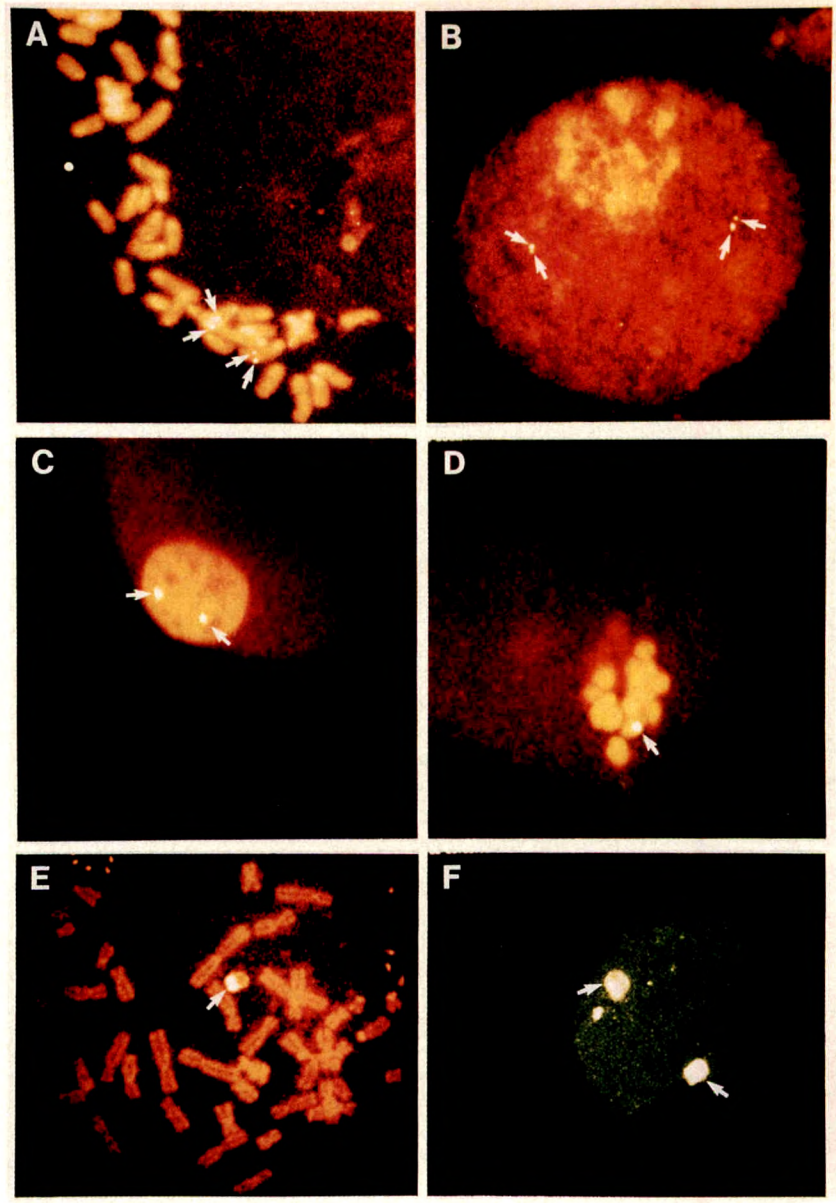

Fig. 2. Panel A, In situ hybridization to metaphase spread with cosmid clone that maps to chromosome 3 (sodium-potassium adenosine triphosphatase gene. **Panel B,** In situ hybridization to mouse blastomere with cosmid clone that maps to chromosome 3 (sodium-potassium adenosine triphosphatase gene). **Panel C,** In situ hybridiztion to mouse blastomere with X-specific repeat probe. Two signals are present consistent with XX karyotype. **Panel D,** In situ hybridization to mouse blastomere with X-specific repeat probe. This blastomere is in metaphase and has one signal. **Panel E,** In situ hybridization to human metaphase spread with Y-specific repeat probe; one signal is noted. **Panel F,** In situ hybridization with Y-specific repeat probe to blastomere from polyspermic human preembryo that has two major signals consistent with XYY karyotype. Two other cells from this preembryo also had two signals each.

ization performed in our laboratory. In addition to salmon sperm DNA, mouse total genomic DNA was added to suppress repetitive sequences in the probe DNA. The probe mixtures contained 20% dextran sulfate and 2X sterile saline citrate. Slides and probe were denatured separately. After denaturation for 2 minutes at 70° C in 20% formamide/2X sterile saline citrate, slides were dehydrated through a cold ethanol series and allowed to air dry. Probe mixtures were denatured at 75° C for 5 minutes followed by ice (for repeat probes) or a 37° C incubation for probes that required suppression.[2] Ten microliters of denatured probe was applied to the slide, coverslips were applied and sealed, and the slides were incubated overnight at 37° C. Slides were incubated for 5 minutes three times each in 50% formamide/2X sterile saline citrate at 42° C, then 5

minutes at 60° C three times in 0.1X sterile saline citrate. They were blocked for 30 minutes at 37° C in 3% bovine serum albumin, 4X sterile saline citrate, and 0.1% Tween 20 polysorbate preparation. Biotinylated probes were detected by incubation with fluorescein isothiocyanate–avidin (Vector Laboratories) diluted to 50 μg/ml in 1% bovine serum albumin, 4X sterile saline citrate, and 0.1% Tween 20 polysorbate preparation at 37° C for 30 minutes. After washing three times for 5 minutes in 4X sterile saline citrate, 0.1% Tween 20 polysorbate preparation at 42° C, slides were mounted with glycerol containing propidium iodide as counterstain and 1,4-diazabicyclo(2.2.2)octane (DABCO, Sigma Chemical Co., St. Louis) to reduce photobleaching. The total time required for preembryo biopsy, fixation, and in situ hybridization of blastomeres is approximately 48 hours.

Results

The embryo biopsy technique described is pictorially represented in Fig. 1, *panels A to E*. A slit was made in the zona pellucida of mouse preembryos at the four-cell stage with a holding pipette and a fine sharpened microneedle (Fig. 1, *panel A*). After the slit was made a biopsy pipette was inserted into the slit (Fig. 1, *panel B*) and gentle suction was applied. Gentle manipulation was used to tease the blastomere from the surrounding blastomeres and through the zona slit (Fig. 1, *panels C and D*). Finally the blastomere and the embryo were released into the media (Fig. 1, *panel E*). The embryo was passed serially through fresh media and cultured under oil at 37° C in 5% carbon dioxide. Embryos manipulated and cultured in this fashion continued to develop and form blastocysts in the majority of cases (Fig. 1, *panel F*).

A series of embryo biopsy experiments are summarized in Table I. The majority of embryos (84%) cultured in our system proceeded to the blastocyst stage. The manipulations required for partial zona dissection did not inhibit embryo growth inasmuch as approximately 90% of embryos treated in this fashion proceeded to blastocyst. The additional steps required to remove a blastomere had a minimal negative impact on the ability of preembryos to develop into blastocysts as 74% continued to divide. Blastocysts from preembryos that underwent biopsy were morphologically indistinguishable from control blastocysts except that the slit in the zona was sometimes apparent. Occasionally the total size of the blastocyst was somewhat smaller with preembryos from which biopsy specimens were obtained but this was not a consistent finding. Later embryo biopsy experiments were performed with a modified biopsy medium that contained bovine serum albumin (0.2%) and sucrose (0.1 mol/L). A series of 31 biopsies performed in this media resulted in an 84% blastocyst rate.

PDZ, Partial zona dissection. Embryos were placed in biopsy media (calcium- and magnesium-free phosphate-buffered saline solution with 0.1% EDTA) and partial zona dissection was performed by the method of Malter and Cohen. Embryos from which biopsies had been obtained had a biopsy pipette placed inside the zona and a blastomere was removed (see Fig. 1, panels A to F).

Fig. 2, *panel A*, shows a metaphase spread of mouse chromosome that had been subjected to in situ hybridization with a probe that hybridizes to the sodium and potassium adenosine triphosphatase gene on chromosome 3. This probe had been nick translated in the presence of biotinylated dUTP, which specifically incorporated biotin into the probe. After in situ hybridization with this probe fluoresceine isothiocyanate–linked to avidin was incubated with the slide allowing the specific avidin-biotin interaction to label the DNA sequence of interest with a fluorescent probe. Signal was then visualized with a laser-scanning confocal microscope and an image was constructed by an image processor with data recorded by a photomultiplier detector. The image obtained shows signal on both chromatids of each copy of chromosome 3 (four total signals). Fig. 2, *panel B* shows the same probe hybridized to a blastomere obtained by preembryo manipulation. Two signal domains are noted in this interphase nu-

cleus. Specifically this cell is in the G2 phase in which the synthesis phase has duplicated the chromatids, thus each signal domain has a bilobed configuration. Comparison of metaphase chromosomes with interphase nuclei shows the same signal domains.

Fig. 2, *panel C*, shows a blastomere that has been hybridized with a probe that specifically labels the centromeric portion of the X chromosome. There are two clear signals consistent with a female karyotype. Fig. 2, *panel D*, shows a blastomere hybridized with the X probe that happens to be in metaphase. There is one clear signal consistent with a male karyotype. Even though this cell is in metaphase, in situ hybridization allows one to analyze the DNA for the signal of interest. Finally, Fig. 2, *panel E*, shows a human male metaphase spread hybridized with a chromosome Y–specific probe. One clear signal domain is apparent. In situ hybridization to a blastomere from a human polyspermic embryo is shown in Fig. 2, *panel F*. Two clear major signal domains are noted. Two other cells from this same preembryo had two clear signals as well (data not shown) and presumably this represents an XYY karyotype.

Comment

The revolution in molecular genetics will provide medical science with sophisticated, more sensitive methods for prenatal genetic diagnosis. Assisted reproductive technology has provided access to the human preimplantation embryo. The combination of these two disciplines will allow genetic diagnoses before implantation. The extension of prenatal diagnosis to the preimplantation period will enable fertile patients at genetic risk who would not otherwise opt for abortion to use assisted reproductive techniques to select only those embryos that are not at risk of carrying genetic diseases. The success of this technology as a medical diagnostic discipline requires the development of techniques that will reliably and specifically predict genetic outcome. Polymerase chain reaction has enabled one to specifically amplify DNA sequences of interest over one-millionfold. This technique allows the diagnosis of gene-specific disorders such as cystic fibrosis, sickle cell anemia, Duchenne-type muscular dystrophy, and others. Polymerase chain reaction is limited by the ability of small fragments of contaminating DNA sequences to interfere with a reliable diagnosis. Some of these concerns have been overcome by the development of techniques to prevent this problem. Polymerase chain reaction will not allow one to make a diagnosis in which numeric chromosome analysis is concerned. Karyotype analysis of single cells is not practical because it is limited to metaphase and requires a large number of cells. In situ hybridization is the only technique that will permit analysis of chromosome number in the single cell or small numbers of cells. The development of the capability to detect a number of chromosomes simultaneously (e.g., 13, 16, 18, 21, X, and Y) with different fluorescent-labeled probes is being pursued. This article is the first publication of which we are aware that shows in situ hybridization to blastomeres obtained from embryo micromanipulation. Although the techniques need further refinement before becoming clinically applicable this article shows the potential for the use of in situ hybridization as a tool for preimplantation diagnosis.

Embryo biopsy techniques are being pursued by a number of investigators. Most involve the puncture of the zona pellucida by a sharpened pipette of fine caliber and removal of a blastomere. A critical factor in successful embryo biopsy is the media in which the procedure takes place. We used a phosphate-buffered saline solution that is calcium- and magnesium-free. In addition, a small amount of chelating agent is also used. Both promote the disaggregation of blastomeres. Later experiments were done in the presence of sucrose and bovine serum albumin, which contributed to the ability to obtain an intact blastomere by shrinking it with sucrose and preventing its adherence to the pipettes with albumin. The use of a fine microneedle to make a controlled slit in the zona (partial zona dissection) allows the entry of the biopsy pipette into the preembryo with minimal trauma to the blastomeres. Although this technique requires one to change pipettes to complete the procedure the viability of the preembryo after manipulation is as good as some investigators and better than others. This method of embryo biopsy offers an alternative to methods previously published.

All studies to date that use preembryo biopsy analyzed blastomeres by polymerase chain reaction. Whereas polymerase chain reaction is efficient and reliable it is unable to detect aneuploidy and is hampered by contamination. Visualization of the nuclear material directly in the nucleus allows one to perform numeric chromosome analysis without the problem of contamination. At present our method is not efficient enough to be used clinically. Specifically, the ability to retain an intact blastomere on a glass slide through the in situ hybridization procedure is an inefficient process with $<25\%$ success. Focused efforts to alleviate this problem are under investigation.

In this study, in situ hybridization with various gene probes indicates that even one blastomere from which a biopsy specimen has been obtained may be sufficient to localize the gene. In our study, the adenosine triphosphatase gene on chromosome 3 and the X chromosome repeat probe were localized. An important feature of this procedure is that genes and chromosomes can be localized in interphase nuclei and metaphase chromosomes. In the future it will be possible to localize various other genes and chromosomes of interest

as new probes become available. Human repeat sequences and human chromosome libraries, which are chromosome-specific, are currently available for most chromosomes thus numeric chromosome analysis is a potential clinical application of this technique. Therefore coupling of preembryo biopsy and in situ hybridization may be an important dimension in the development of new procedures for prevention of hereditary disease.

We thank Dr. Maurice J. Mahoney for helpful comments and Drs. Christine Disteche and David Housman for providing probe sets. We also thank Jacques Cohen, PhD, and Henry Malter for teaching us partial zona dissection and Julia Logan, Lorrie Bowen, Joan Menninger, and M.Y. Chang, MD, for technical assistance. Finally, the Carl Zeiss Company generously provided us with equipment and technical support.

Factors affecting embryo implantation after human in vitro fertilization: A hypothesis

Richard J. Paulson, MD, Mark V. Sauer, MD, and Rogerio A. Lobo, MD

Los Angeles, California

In the clinical practice of human in vitro fertilization, pregnancy is dependent on embryo implantation. Pregnancy is a function of the number of embryos transferred, with multiple embryos resulting in a higher likelihood of pregnancy. We formulated a mathematic model of embryo implantation. This model describes embryo implantation as dependent on three factors—transfer efficiency, embryo quality, and endometrial receptivity. Application of existing embryo implantation data to this model allows the calculation of the approximate value of each of these factors. On the basis of historic data, data obtained from our in vitro fertilization program, and these theoretic considerations, it is our hypothesis that (1) there is an inherent inefficiency associated with the mechanical transfer of embryos into the uterine cavity, which limits the maximal embryo implantation rate; (2) the quality of embryos produced by controlled ovarian hyperstimulation, follicle aspiration, and in vitro fertilization is very high and approaches that of embryos produced in natural cycles in vivo; and (3) endometrial receptivity is markedly diminished in stimulated cycles and is the current rate-limiting step of pregnancy success of in vitro fertilization. (AM J OBSTET GYNECOL 1990;163:2020-23.)

Key words: Embryo implantation, in vitro fertilization, unstimulated in vitro fertilization, endometrial receptivity, oocyte donation

In the clinical practice of human in vitro fertilization (IVF) the majority of pregnancy failures occurs after embryo transfer. Whereas the majority of patients achieve oocyte recovery, fertilization, and cleavage of embryos, only a small proportion of transferred embryos actually implant and result in viable pregnancies. Thus pregnancy after IVF and embryo transfer is dependent on embryo implantation. Furthermore, the pregnancy rate is known to increase when multiple embryos are transferred.[1]

It has been suggested that in the first approximation, embryo implantation can be treated as an independent event.[2] When multiple embryos are transferred, the implantation of one embryo neither inhibits nor enhances the implantation of any of the other embryos. This assumption leads to the equation:

$$P = 1 - (1 - EI)^n$$

where P is pregnancy, EI is the likelihood of implantation of an individual embryo, and n is the number of embryos transferred.[2]

6/6/24778

We developed a mathematic model for embryo implantation based on the tenet that embryo implantation is an independent event and we described embryo implantation as consisting of three separate components with individual values that vary under specific clinical conditions.

The purpose of this article is to present our mathematic model of factors that affect embryo implantation, to analyze available embryo implantation data in an effort to test and validate this model, and to determine the relative contribution of each of the putative factors under specific clinical conditions.

Material and methods

To develop our hypothesis of factors that affect embryo implantation, we followed three steps. First, we considered previous mathematic formulations and expounded on them. Second, we used embryo implantation data from published sources to modify our model and to help express a maximal attainable rate for embryo implantation. Finally, we examined embryo implantation data from three groups of patients in our own IVF program to test our hypothesis and to assign specific values to the components of the embryo implantation equation.

Hypothesis. The concepts of embryo quality and endometrial receptivity have been used to describe pregnancy success[2, 3]:

Embryo implantation = Embryo quality × endometrial receptivity

Whereas ideal embryo quality and endometrial receptivity may inevitably lead to embryo implantation in vivo, we do not believe that the same will occur when embryos undergo extracorporeal manipulation and mechanical transfer to the uterus. Therefore we chose to group the factors that affect embryo implantation into three general categories including the previously introduced concepts of embryo quality and endometrial receptivity and add a third term, that of *transfer efficiency*. The latter term quantifies the failure of embryo implantation resulting from the embryo transfer process itself. Thus in the first formulation we have:

$$\text{Embryo implantation} = \text{Embryo quality} \times \text{endometrial receptivity} \times \text{transfer efficiency}$$

Transfer efficiency. Transfer efficiency is a term that may be different under different circumstances. It may vary with transfer catheters, the position of the patient, the clinician who performs the transfer, and the different routes of embryo transfer, such as transcervical versus the fallopian tubes. Therefore in estimating this value we chose to focus on implantations after embryo transfer by the transcervical route because this is the most commonly used technique in both our program and in most other institutions. Because transfer efficiency is equal to embryo implantation when both embryo quality and endometrial receptivity are optimal, we thought the best approximation to this value would be obtained by examination of the implantation rates after the synchronous transfer in natural cycles of in vivo fertilized blastocysts. We are aware of two published series in human beings that address this issue.[4, 5] Buster et al.[4] reported implantations in two of four blastocysts transferred. Formigli et al.[5] reported implantations in four of six expanded blastocysts transferred and in six of 11 embryos transferred at the morula stage or thereafter, suggesting a range of 50% to 67% for transfer efficiency in human patients. In animals, reported embryo implantation rates after transcervical transfer of in vivo fertilized blastocysts obtained by uterine flushing are in the range of 50% to 75%.[6] Therefore as a best estimate we believe that with experienced clinicians the approximate value of transfer efficiency for transcervical embryo transfer is 60%.

After updating our formula we now have:

$$\text{Embryo implantation} = \text{Transfer efficiency} \times \text{embryo quality} \times \text{endometrial receptivity}$$

$$\text{Transfer efficiency} = 0.6$$

$$\text{Embryo implantation} = 0.60 \times \text{embryo quality} \times \text{endometrial receptivity}$$

Embryo quality. Because an in vivo fertilized blastocyst is considered to have an embryo quality value of 1, and not all 48-hour embryos become blastocysts, a correction term is needed to account for the clinical practice of transferring embryos 48 hours after follicle aspiration. This term is the percentage of 2-day embryos that progress to the blastocyst stage and provides the maximum quality value that can be assigned to an embryo after 48 hours of development.

In the most commonly used animal model, the mouse, in vivo fertilized embryos collected at the 1- or 2-cell stage progress to blastocyst in about 75% of cases.[7] In human beings, IVF embryo freezing studies reported about a 25% progression to blastocyst, although this number would probably be higher if all embryos were cultured rather than only those that remain after fresh embryo transfer.[8] On the basis of these admittedly scant data, we chose to estimate the percent progression to blastocyst of 48-hour old human embryos at 60%.

Restatement of our original formula:

$$\text{Embryo implantation} = \text{Transfer efficiency} \times \text{embryo quality} \times \text{endometrial receptivity}$$

$$\text{Embryo quality (corrected)} = 0.6 \times \text{embryo quality}$$

$$\text{(Transfer efficiency} = 60\%\text{, as stated in the preceding section)}$$

With these estimates,

$$\text{Embryo implantation} = 0.36 \times \text{embryo quality} \times \text{endometrial receptivity}$$

and thus when embryo quality and endometrial receptivity are optimized,

$$\text{Embryo implantation} = 36\%$$

With this theoretic formulation, we now analyzed embryo implantation data from our IVF program in an effort to test and apply our hypothesis.

Patient selection. Embryo implantation data was obtained in a retrospective fashion from three groups of patients in our program.[9-11] Our nonanonymous donor oocyte program provides a unique model of embryo implantation because it is conducted in a manner identical to standard IVF.[9] In particular, ovarian stimulation and follicle aspiration regimens are identical and all resultant embryos are available for transfer and thus provide embryos of quality similar to that of standard IVF. Embryos are transferred to the uteri of agonadal recipients receiving exogenous estradiol and progesterone whose endometrial histology is synchronous as proved by biopsy in a prior replacement cycle. A total of 18 cycles were conducted between January 1988 and June 1989 with donors who were 35 years old or younger and who had conceived at least once previously. From our standard IVF program, we selected for analysis cycles that we thought would result in embryo quality identical to that of the donor cycles.[10] We considered only patients who were 35 years old or younger, who

‖Unstimulated cycles triggered with hCG. Only embryos derived from successfully aspirated dominant follicles were considered.[11]

had conceived at least once previously, and in whom pelvic factor was the sole or predominant cause of infertility. A total of 54 such cycles were conducted during the same 18-month period. These data were previously reported in detail.[10] The third group consisted of patients undergoing embryo transfer in unstimulated IVF cycles during January 1988 to December 1989. The unstimulated IVF protocol was previously described.[11, 12] Briefly, it is offered to normally ovulatory patients with pelvic factor whose follicular development in a spontaneous cycle is monitored with serial ultrasonographic examination. Human chorionic gonadotropin (hCG) is administered when the follicle reaches maturity criteria. In this analysis, we considered only the 24 cycles in which embryos that resulted from successfully aspirated dominant follicles were transferred.

Results

Table I depicts the total number of embryos transferred, the total number of implantations, the individual embryo implantation rate, and the clinical pregnancy rate in the donor oocyte, standard, and unstimulated IVF groups.[9-11] As a result of the matching between the donor and standard IVF groups, a similar number of embryos of similar morphologic quality were obtained and transferred in each of these cycles.[10] In the donor group, 75 total embryos were transferred and 26 implanted, for an embryo implantation rate of 35% and a clinical pregnancy rate of 67%. In the standard IVF group, 225 embryos were transferred and 24 of these were implanted for an embryo implantation rate of 11% and a clinical pregnancy rate of 39%. These differences are statistically significant ($p < 0.05$). In the unstimulated group, 24 transferred embryos resulted in five implantations or a 21% implantation rate, which was significantly higher than that of the stimulated cycles ($p < 0.05$). (Clinical pregnancy rates are presented for completeness but are not included in the implantation analysis.)

Comment

Values for embryo quality and endometrial receptivity can now be approximated. In the donor IVF group:

$$\text{Embryo implantation} = 0.35$$
$$\text{Embryo implantation} = 0.36 \times \text{embryo quality} \times \text{endometrial receptivity}$$

implying that

$$\text{Embryo quality} \sim 1$$
$$\text{Embryo receptivity} \sim 1$$

That endometrial recptivity is optimal is not surprising because the endometrial histology had been optimized. However, if embryo quality is also optimal, this means that current stimulation regimens are capable of producing embryos of a quality that is, at least among those embryos selected for transfer, comparable to that of embryos produced in vivo during natural cycles.

In the standard IVF group:

$$\text{Embryo implantation} = 0.11$$
$$\text{Embryo implantation} = 0.36 \times \text{embryo quality} \times \text{endometrial receptivity}$$

thus

$$\text{Embryo quality} \times \text{endometrial receptivity} \sim 0.33$$

However, by design:

$$\text{Embryo quality (standard IVF)} = \text{Embryo quality (donor IVF)} = 1$$

implying that

$$\text{Embryo receptivity (standard IVF)} = 0.33$$

This difference in endometrial receptivity between standard IVF and donor IVF cycles implies that in stimulated cycles, endometrial receptivity is the principal limiting factor of embryo implantation[10] and that as many as two thirds of transferred embryos capable of implanting fail to do so as a result of decreased endometrial receptivity.

In the unstimulated IVF group:

$$\text{Embryo implantation} = 21\%$$
$$\text{Embryo implantation} = 0.36 \times \text{embryo quality} \times \text{endometrial receptivity}$$

thus

$$\text{Embryo quality} \times \text{endometrial receptivity} = 0.60$$

There is no clear way to assign relative value to embryo quality and endometrial receptivity in this case. However, because steroid levels and their patterns of change in these cycles are essentially natural, it seems

reasonable to assume that endometrial receptivity is uncompromised. If that is true, then

$$\text{Embryo quality} = 0.60$$

Because hCG is administered in these cycles before the onset of the luteinizing hormone surge, this diminished embryo quality value may be explained as reflective of incorrect timing of hCG administration, with resultant diminished oocyte quality.

Our formula and the derived approximate values for transfer efficiency, embryo quality, and endometrial receptivity are not to be taken literally. Rather, it is our intent to attempt to explain the differences in embryo implantation rates that we observed in our program and in the reports of others. We believe that the concept of transfer efficiency is an important addition to the previously introduced embryo quality and endometrial receptivity and may help to explain some of the differences in implantation rates observed under different clinical circumstances and help to define a maximal embryo implantation rate. We also tried to extrapolate from available data the approximate value of the maximal embryo implantation rate that can be expected with current techniques. We estimated this value at 36%. This number matches closely the embryo implantation rates observed in our donor oocyte IVF program. This observation led us to the conclusion that selected embryos obtained from fertilization in vitro of oocytes obtained from hyperstimulated cycles are of a quality that approximates that of in vivo fertilized embryos in natural cycles. Under the scrutiny of time and as additional data become available, the approximate values in this article will likely have to be modified. We present them as a first approximation and as a stimulus to further exploration of this topic.

Prediction of residual trophoblastic tissue in first-trimester abortions: The role of transvaginal Doppler ultrasonography

To the Editors: Schiff and colleagues[3] excellent article on the prediction of residual trophoblast (Schiff E, Ben-Baruch G, Moran O, et al. Prediction of residual trophoblastic tissue in first-trimester abortions and low levels of human chorionic gonadotropin β-subunit. AM J OBSTET GYNECOL 1990;162:797-801) illustrates the importance of a clinical scoring system in the management of first-trimester abortions. I would like to suggest transvaginal pulsed Doppler ultrasonography as an additional useful diagnostic tool for the diagnosis of residual trophoblastic tissue in these patients.

Transvaginal pulsed Doppler ultrasonography has a great advantage potential over routine ultrasonography in tissue characterization because it can display functional flow in addition to structure. Pulsed-wave Doppler ultrasonography allows direct and precise visualization of the sample volume where the flow is to be studied. When Doppler ultrasonography is mounted on a high-frequency transvaginal transducer (6.5 to 7 MHz) it is possible to study flow even in very small structures. In normal and abnormal pregnancies the

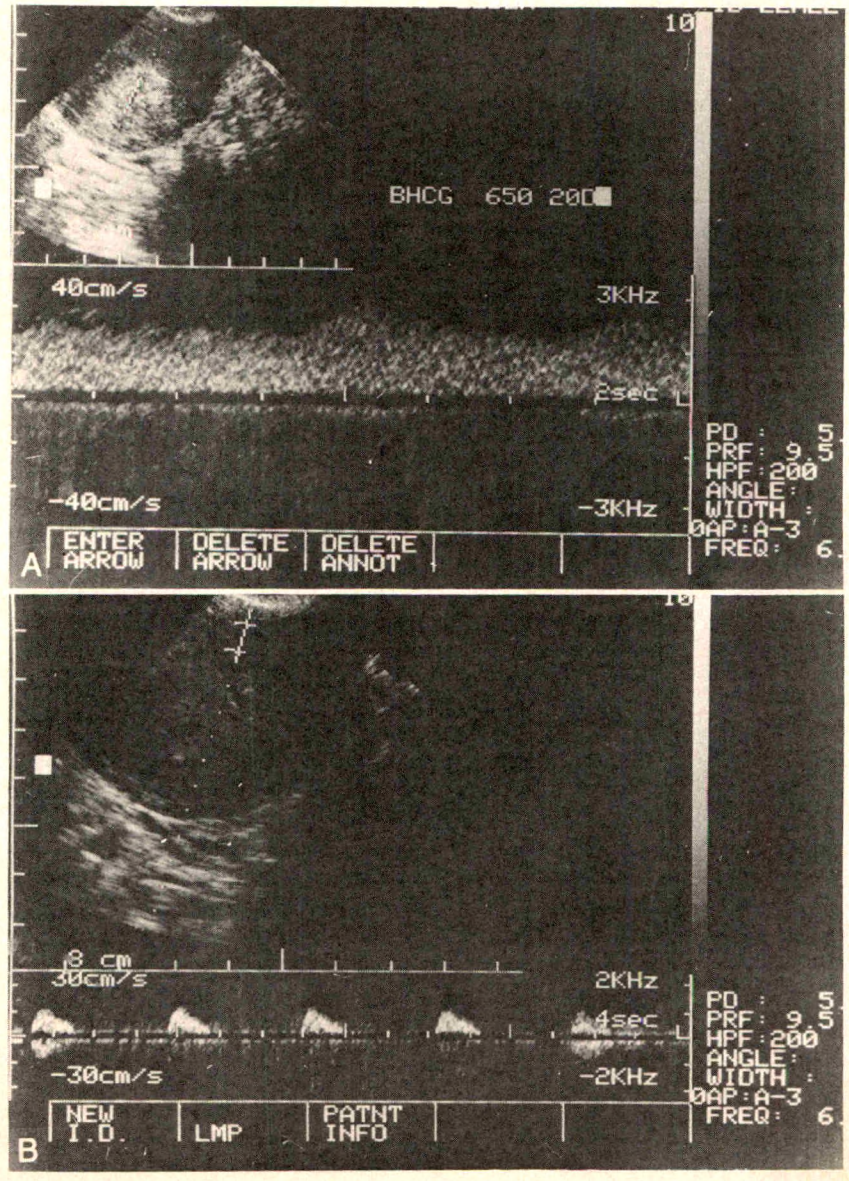

Fig. 1. Ultrasonographic duplex examination of the uterus. **A,** Doppler gate positioned into echogenic tissue. Low-impedance signal appearing during diastole is characteristic of trophoblastic flow. **B,** Intramyometrial Doppler gate shows absence of diastolic flow, consistent with higher distal vascular impedance that is characteristic of nonpregnant arcuate artery.

peritrophoblastic area, which is composed of lacunar (intervillous) spaces devoid of arteriolar muscle in their walls, generates a low-impedance signal during diastole because of its low peripheral resistance.[1] Because histologic examination of the residual trophoblastic tissue shows villi and spaces distended with blood, it is possible to obtain low-impedance signal that is characteristic of placental flow.

The following case illustrates the feasibility of transvaginal pulsed Doppler ultrasonography in assessment of residual trophoblast in first-trimester abortion. Twenty days after curettage for first-trimester abortion the patient had persistent vaginal bleeding. Human chorionic gonadotropin β-subunit was 650 mIU/ml. Transvaginal ultrasonography showed intracavitary echogenic material that might be blood clots or residual trophoblast. Pulsed Doppler investigation of this area clearly depicated low-impedance diastolic signal compatible with trophoblast (Fig. 1). Trophoblastic tissue was obtained by repeated curettage.

Incorporation of transvaginal pulsed Doppler ultrasonography into the proposed scoring system as described by Schiff et al. might be beneficial in improving its diagnostic sensitivity thus reducing unnecessary surgical interventions in the management of first-trimester abortions. Therefore I recommend routine use of transvaginal pulsed Doppler ultrasonography in patients suspected of residual trophoblastic tissue.

Suprapubic or vaginal procedure

To the Editors: We refer to Dr. Arieh Bergman and collaborators' articles (Bergman A., Ballard CA, Koonings PP. Comparison of three different surgical procedures for genuine stress incontinence: prospective randomized study. Am J Obstet Gynecol 1989;160:1102-6) and (Bergman A, Koonings PP, Ballard CA. Primary stress urinary incontinence and pelvic relaxation: prospective randomized comparison of three different operations. Am J Obstet Gynecol 1989;161:97-101). The conclusion is the indubitable superiority of the retropubic procedure in all stress urinary incontinence cases, with or without significant descensus. Seemingly, with a procedure that has a probability of one failure in ten cases, it would be almost malpractice to choose another method with a failure rate of nearly one to three. There is no unanimity with regard to such a marked difference, nor does it confirm our experience with over 500 incontinence operations. More significantly, we believe that the authors' manner to attain this conclusion is not probatory.

Random selection means no selection at all. In the great variety of stress urinary incontinence clinical manifestations, certain criteria give a fairly good orientation on the probable success of vaginal operations. Marked descensus, good accessibility, and good tissular turgor make the vaginal procedure promising. Random selection implies that some patients have undergone vaginal surgery without the aforementioned conditions. Possibly, most gynecologists would prefer suprapubic operations in these cases, this affecting success and failure rates. Bladder neck stabilization does not reach the same extent in the vaginal procedure as in the suprapubic approach. Yet, this may not be necessary. Other factors may intervene.

The critical Q-tip test angle given in the two articles is 30° to 35°. In large series we observed that the critical angle is not the same for both operations. Angles of 25° generally suffice in vaginal operations but frequently result in failure in the suprapubic method. Several factors may explain this difference, independently of bladder neck stabilization. Two are mentioned: the kinking of the urethra and the diminished rectal pressure-transmission in the suprapubic approach are very convincing in the Burch modification, which builds a fibrous wall from one Cooper's ligament to the other, englobing the posterior vaginal vault. Perhaps there is another factor. With a sudden raise of the intraabdominal pressure there may be an instantaneous engorgement of the periurethral veins acting as a veinous cushion increasing urethral pressure, apparently remaining in the vaginal operation, and, to a high degree, obliterated in suprapubic surgery. This may account for the differences we observed in the effective angles between the vaginal and the suprapubic procedures.

With rigorous selection, we believe there is room left for stress urinary incontinence vaginal corrections. The anatomic superiority of bladder neck stabilizations in the suprapubic procedure does not invariably mean functional superiority.

Reply

To the Editors: We thank Drs. Cabrera, Ospitia, and Szekely for their interest in our articles. These articles indeed indicate that in our hands the abdominal retropubic procedures resulted in a better cure rate than that of the vaginal operations in women with stress incontinence. However, it is a total misinterpretation of the articles to suggest that the vaginal procedures should not be done. We mention in the articles that some authors such as Beck with anterior colporrhaphy[1] or Leach et al. with modified Pereyra procedure[2] achieved good results. These authors modified the "original" technique, resulting in good cure rates.

Our study was designed as a randomized prospective study and random selection of the patients is a key factor in it. In many retrospective studies, women with marked pelvic relaxation (many of whom had more severe degrees of stress urinary incontinence) underwent vaginal operation whereas many women with mild pelvic relaxation underwent abdominal procedures, making the comparison unfair.

Women with no pelvic relaxation and well-supported pelvic organs usually do not have stress urinary incontinence and the few exceptions who do, should not undergo a procedure for bladder neck suspension.[3] However, we clearly indicated in the first article[1] that all women in this study had some degree of pelvic relaxation and all of them had positive Q-tip test results of ≥35°. With these criteria, we believe that randomizing patients to the various procedures is the most meaningful way to conduct such a study.

The theory about the superiority of the vaginal procedures that enable the periurethral veins to remain engorged, as opposed to the abdominal procedures, is very interesting, but remains to be proven. In the comment section of our articles we state clearly that there is definitely room for the vaginal procedures for stress urinary incontinence. The surgeon's experience and the patient's general condition are very important factors to consider. However, in comparing the anterior colporrhaphy or Pereyra procedure with the Burch operation, the latter in our hands resulted in better cure rate.

Tubal embryo successfully transferred in utero

To the Editors: Until fairly recent times, the multifarious aspects of in vitro fertilization, embryo handling, and gamete intrafallopian transfer many would have considered hardly conceivable. In view of all the developments, it is considered timely to report that in the Gifford Memorial Hospital, Randolph, Vermont, in 1980, a 27-year-old patient with unaccountable infertility and regular 28-day cycles had intercourse around the middle of the month. Approximately 4 weeks later severe pain developed in the region of the left fallopian tube. There was no uterine bleeding and the pregnancy test was positive. Her history and all laboratory test results were normal. Abdominopelvic examination revealed no appreciable uterine enlargement or discernible abnormalities, only severe pain elicited with palpation in the tubal area.

Exploration while the patient was under regional anesthesia revealed a single corpus luteum in the left ovary, some uterine congestion, and on direct palpation of the left tube a small, 4 to 5 mm mass. With careful incision into the tubal lumen an intact embryonic sac was easily enucleated, still completely covered with chorionic villi, even at 40 days, as shown in Fig. 1. It was immediately placed in oxygenated saline solution warmed to body temperature. A segment of infusion tubing was cut, one end slanting and the other attachable to a glass Presto syringe with a large rubber bulb enabling one to aspirate or express as desired. With gentle suction the slanted end of the tubing was passed into the myometrium in the upper, anterior aspect of the uterus until discernible decidual tissue was observed. With the tubing in situ, the embryonic sac was taken up into the glass syringe, which was then attached to the tubing and expressed in utero. Tamponade of the puncture site with a very warm pad controlled any bleeding. The tube was then repaired and the abdomen closed. The pregnancy test remained positive. After normal postoperative and prenatal courses, a normal infant was delivered at term.

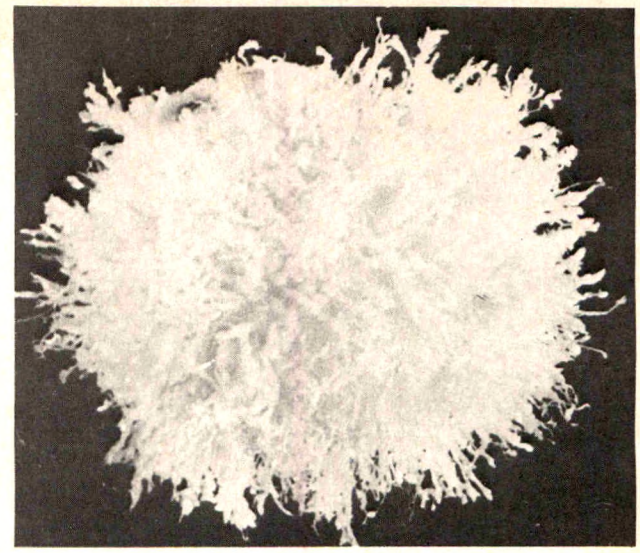

Fig. 1. Human chorionic sac still completely covered with villi at 40 days. (From Rugh R, Shettles LB. From conception to birth: the drama of life's beginnings. New York: Harper & Row, 1971.)

The above was considered the first transfer of a tubal embryo in utero with successful outcome, until recently. Dr. A. P. D. Rosa of São Paulo, Brazil, cites a case he discovered by Dr. C. J. Wallace.[1] The patient underwent a myomectomy and an undiagnosed tubal pregnancy was found. With the myomectomy completed, an "olive size" gestational sac was easily removed and securely placed in utero. After closure of the uterus, the tube, and the abdomen and with uneventful postoperative and prenatal course, a normal infant was delivered at term.

With his case and the one cited, it would appear that with the intact, early embryonic sac still covered with

the full complement of chorionic villi, free of hemorrhage, transfer in utero may prove successful and merits a try, especially in the childless patient.

Use of midforceps applauded

To the Editors: I congratulate Dr. R. A. Bashore on his excellent presentation (A comparison of the morbidity of midforceps and cesarean delivery. AM J OBSTET GYNECOL 1990;162:1428-35.). It is satisfying to see prominent obstetricians doing something to bring clear facts about the advantages of midforceps delivery.

With reference to the 3-hour second stage of labor, I feel better with the classic 2 hours. In special cases of dystocia with good fetal heart tones and epidural anesthesia, the 3 hours are okay. I have seen it longer than that, although contractions every 3 minutes for a longer time bother me because there is no progress and the fetal head receives the trauma.

I am impressed with Dr. Bashore's assessment of future cesarean morbidity. His concerns were: the morbidity associated with repeat cesarean delivery, repeated blood transfusions, and the risk of uterine rupture. To these I would add increased dyspareunia after the age of 50 years and the risk of unusual bleeding when doing a curettage if care is not taken that the curette does not touch the lower anterior cervical segment.

I applaud his guidelines to ensure the prudent use of midforceps. If I were to add my input, I suggest the posterior and transverse position be rotated by the Ramirez technique, which is less traumatic. In dystocia cases, this rotation can be done without anesthesia, the labor is allowed to continue, and later on, if a spontaneous delivery does not occur, you will be doing a forceps delivery at a much lower station and to an anterior position. I suggest that there is a need for a more objective and accurate method to evaluate the presenting part station. The method at present is subjective and inaccurate. On this same point, sometimes I estimate +2, and a few minutes later, I estimate 0 station. We have to be careful with it.

I could not agree more with Dr. Bashore's quest to remove "some of the stigma associated with the use of midforceps without a loss of respect for the procedure."

Findings not new

To the Editors: We note with interest the findings of Langer et al. (Langer O, Levy J, Brustman L, Anyaegbunam A, Merkatz R, Divon M. Glycemic control in gestational diabetes mellitis—How tight is tight enough: Small for gestational age versus large for gestational age? AM J OBSTET GYNECOL 1989;161:646-53) who report a correlation between levels of control of maternal glucose and fetal size at birth in mothers diagnosed to have gestational diabetes. They found that when mean maternal blood glucose values are high (>105 mg/dl) there is a significantly increased incidence of large-for-gestational-age infants, whereas in the group with low maternal blood glucose values (mean <86 mg/dl) small-for-gestational-age infants were more likely.

Whereas we are in agreement with the significance of these observations, we write to assert for the benefit of your readers that these findings are not new, and more importantly that hypoglycemia in the whole population of pregnant women (not only those with diabetes) is associated with fetal growth retardation and unfavorable perinatal outcome. Karlsson and Kjellmer reported in 1972[1] of the association between fetal outcome and glycemic control in diabetic mothers, and we have reported regularly from the Mercy Maternity Hospital since the early 1970s of the association between maternal plasma glucose levels and perinatal mortality and morbidity including fetal size and malformations.[2-5]

Our studies were conducted on a pregnant population with oral glucose tolerance routinely tested during the third trimester, not just those patients with criteria that suggested an increased probability of diabetes. Percentile distributions of plasma glucose levels were used to define hypoglycemia and hyperglycemia, and analysis of the obstetric results in 5000 consecutive patients showed that hypoglycemia had a significant association with subnormal estriol excretion, fetal and placental growth retardation, some fetal malformations, and increased perinatal mortality. When there was hyperglycemia placental growth was stimulated, there as an increased incidence of malformations, and perinatal mortality was increased. We found that hyperglycemia of itself was not associated with an increased incidence of large-for-dates infants, although that observation was confirmed in those patients whose glucose tolerance tests showed defined gestational diabetes. We hypothesized that hypoglycemia is a causal factor in fetal growth retardation and death by restriction of basic substrate necessary for normal fetal growth. We proposed that fetal growth retardation in hypoglycemic mothers may be preventable by administering nutrients to mothers either orally or intravenously.[7]

As pleased as we are that researchers continue to publish information that substantiates our earlier findings, we would be grateful that when authors seek to show originality in their research that they would at least acknowledge those publications that first reported the significance of these observations.

Reply

To the Editors: We were pleased to note the interest and agreement of both Drs. Abell and Beischer on the significance of our findings of the correlation between levels of glycemic control and fetal size in patients with treated gestational diabetes. However, we are disappointed that they failed to comprehend the uniqueness of the study and its originality.

Previously, we documented the need for verified self-monitoring blood glucose data to ascertain accurate and reliable glucose information. Without this method to obtain glucose data, false conclusions could have been drawn in previous studies on the relationship between glucose level and neonatal morbidity. Our current study is the only published report of which we are aware that shows the association between degree of glycemia and pregnancy outcome with the use of verified glucose information.[1,2]

The importance of glycemic control has been emphasized from the late 1960s. Most authors agree that reasonable blood glucose levels should be obtained but there are different opinions as to the target level. One study from Iowa City shows that the prognosis was better for infants when the control of the maternal diabetes was "good" than when it was "poor," but the study failed to define either level.[3] Thus, to the best of our knowledge, no study before ours correlated the specific thresholds of verified mean blood glucose values throughout pregnancy with fetal size. Our study addressed two significant questions: at what level should maternal glucose be maintained to prevent perinatal morbidity in gestational diabetes? and can "tight" control limit fetal growth?

The references that Drs. Abell and Beischer cited to emphasize their argument are unrelated to the research question addressed in our study. Karlsson et al.[4] primarily studied insulin-dependent patients and not those with gestational diabetes. Their study was retrospective covering a 10-year period (1961 to 1970) before the establishment of self-monitoring of blood glucose levels (1980). They reported the association between blood glucose level and perinatal mortality as well as the relationship between mean blood glucose and congenital anomalies. However, they did not assess whether "tight" control can alter fetal growth.

The studies by Abell and Beischer in the early 1970s never addressed the question of at what level should maternal glucose be maintained to prevent perinatal morbidity in gestational women? Their studies originated from a data base that correlated estriol and pregnancy outcome. They further attempted to find an association between oral glucose tolerance test (diagnostic tool) findings and fetal size. The majority of their population did not have diabetes, and the glucose load was 50 gm, not 100 gm as recommended by the National Diabetic Data Group. Thus their data cannot be compared with other studies of oral glucose tolerance tests. They did not report the actual mean blood glucose level throughout pregnancy in their gestational diabetic subjects. They used a diagnostic test result to predict outcome of pregnancy, ignoring the fact that treatment of the gestational diabetic patient will alter mean blood glucose level. Thus test results could not be a predictor when intervention occurred. Results of the oral glucose tolerance test could be used as a potential predictor of fetal size in nondiabetic subjects (no intervention) as they, and others, have shown.[5-8]

We acknowledged preliminary research that had stimulated our hypotheses but we cannot, in this instance, recognize their research, which never addressed or showed the findings we reported. We all like to see ourselves in the literature but there still needs to be justification for the citation.

Explanation of mechanism of Hyskon solution reaction needed

To the Editors: Drs. Jedeikin, Olsfanger, and Kessler's article (Disseminated intravascular coagulopathy and adult respiratory distress syndrome: life-threatening complications of hysteroscopy. AM J OBSTET GYNECOL 1990;162:44-5) is one of several reports of this complication. Whether this complication occurs because of an idiosyncratic reaction to or the intravascular injection of an excessive amount of Hyskon solution, or a combination of these causes has not been determined.

What occurred in this case is clear but the authors need to clarify several factors if we are to have a better understanding of the mechanism of this problem. The article implies that the 1200 ml of Hyskon solution injected into the uterine cavity were retained by the patient. If this is so, how did it occur? Passage of large amounts of Hyskon solution through the fallopian tubes is unlikely because of the viscosity of this material. Intravasation without excessive pressure is unlikely because this was not a surgical hysteroscopic procedure in which vessels were opened. Was it caused by distension with excessive pressures and the intravasation of Hyskon solution through ruptured uterine vessels? How was distension accomplished and what were the resultant pressures? What do the authors believe happened?

Safety of 32% dextran 70 for hysteroscopy

To the Editors: In a recent case report (Jedeikin R, Olsfanger D, Kessler I. Disseminated intravascular coagulopathy and adult respiratory distress syndrome: life-threatening complications of hysteroscopy. AM J OBSTET GYNECOL 1990;162:44-5) the authors claim that alarming symptoms observed in a previously healthy young woman after hysteroscopy were caused by disseminated intravascular coagulopathy and adult respiratory distress syndrome as a result of the use of high-molecular-weight dextran (Hyskon) solution. Neither of these claims is supported by the presented findings. In my opinion this report is an example of the uncritical use of Hyskon solution by surgeons not completely familiar with its properties and other such reports that have been published recently.[1]

It is obvious that during hysteroscopy Hyskon solution may pass into the peritoneal cavity and be absorbed, and also that Hyskon solution may directly enter the circulation during hysteroscopic surgery. It is recommended in the U.S. package insert for Hyskon solution that not more than 500 ml should be instilled and with low pressure to avoid undue passage into the abdomen. In the referred case report Hyskon solution was used in a much higher dosage, but the authors fail to draw the conclusion that the symptoms were caused by the overdosage of Hyskon solution, not by the substance used per se.

Hyskon solution appears to be regarded by many users as an inert distension medium, but it contains dextran 70 and has several pharmacologic effects. 100 ml contains 32 gm of dextran capable of binding 20 ml of water per gram if allowed to enter the circulation. In this case 1200 ml Hyskon solution was instilled during hysteroscopy, after which also laparoscopy was performed. This order of events would promote rapid absorption of dextran from the peritoneal cavity during Trendelenburg position. If 25% of the Hyskon solution used was absorbed 96 gm of dextran would enter the circulation, increasing the blood volume by approximately 2000 ml, an increase that may well precipitate pulmonary edema.

Dextran is widely used as a thromboprophylactic agent. It reduces the Factor VIII–von Willebrand complex. The dextran absorbed should not exceed 1.5 gm/kg body weight, or approximately 300 ml of Hyskon solution. In the referred case the amount of dextran may well have been in excess of this amount, causing a temporary hemostatic defect.

Hyskon solution may on rare occasions cause an anaphylactic reaction,[2] but the symptoms reported to not indicate this. Theoretically such reactions could be prevented by the use of hapten inhibition, which has successfully been applied to prevent anaphylactic reactions from dextrans used intravenously,[3] but the rarity of such reactions with Hyskon solution makes such a procedure questionable.

Karl-Gösta Ljungström, MD, PhD
Department of Surgery, Karolinska Institute, Danderyd Hospital, Danderyd, Sweden S-182 88

Reply

To the Editors: Dr. Ljungstrom concurs that the complications we described may occur after hysteroscopy with Hyskon solution, but makes the point that it is not the substance per se but its overdosage that is responsible for the disseminated intravascular coagulopathy and pulmonary edema. There is no argument that the quantity of Hyskon solution administered was excessive; nevertheless Hyskon solution was the preparation used and Hyskon solution caused the problem, albeit an overdose.

In our case report we did not set out to show the exact mechanism of the problem described; however, we believe that because of the large amount of Hyskon solution injected, a large enough quantity was rapidly absorbed into the circulation via the fallopian tubes and the peritoneal cavity. According to Dr. Ljungstrom, absorption of 25% of the Hyskon solution given would increase blood volume by about 2 L, and occurring over

a short period of time could cause pulmonary edema in healthy persons. On the other hand, the excessive amount of Hyskon solution may have contributed to an adverse drug reaction that manifested by disseminated intravascular coagulopathy and adult respiratory distress syndrome. Further research into the pathophysiology of the toxic effects of Hyskon solution is required to clarify this problem.

The purpose of our article was not to discredit the use of Hyskon solution but to emphasize and to describe the dangers that may occur with the over zealous intrauterine injection of Hyskon solution during simple diagnostic hysteroscopy. All drugs have side effects, and awareness of these complications results in a more intelligent and safer use of these drugs.

Subject index*

A

Abdominal delivery; *see* **Cesarean section**
Abdominal wall
The effect of mode of delivery on the perinatal outcome in fetuses with abdominal wall defects (Moretti et al). 1990;163:833-8
Fetal gastroschisis and omphalocele: Is cesarean section the best mode of delivery? (Lewis et al). 1990;163:773-5
Necrotizing fasciitis of the total abdominal wall after sterilization by partial salpingectomy (Cederna et al). 1990;163:138-9
Ultrasonographic assessment of intestinal damage in fetuses with gastroschisis: Is it of clinical value? (Lenke et al). 1990;163:995-8
Abnormalities
Ascertainment bias in diabetic outcome data (FitzSimmons and Davidson) (Letter); (Damm and Mølsted-Pedersen) (Reply). 1990;163:682-3
The associated anomalies that determine prognosis in congenital omphaloceles (Tucci and Bard). 1990;163:1646-9
The association of single umbilical artery with cytogenetically abnormal pregnancies (Saller et al). 1990;163:922-5
The effect of mode of delivery on the perinatal outcome in fetuses with abdominal wall defects (Moretti et al). 1990;163:833-8
Growth of linear parameters in trisomy 18 fetuses (Droste et al). 1990;163:158-61
In utero detection of cardiac failure from an aneurysm of the vein of Galen (Jeanty et al). 1990;163:50-1
Perinatal outcome of forty-nine pregnancies complicated by acardiac twinning (Moore et al). 1990;163:907-12
Prenatal diagnosis of laryngeal atresia (Watson et al). 1990;163:1456-7
Transvaginal ultrasonographic detection of congenital anomalies in the first trimester (Cullen et al). 1990;163:466-76
Abnormalities, animal
Embryofetal effects of pentamidine isethionate administered to pregnant Sprague-Dawley rats (Harstad et al). 1990;163:912-6
Abortion
Does obstetric ethics have any role in the obstetrician's response to the abortion controversy? (Chervenak and McCullough). 1990;163:1425-9 (Clin. opinion)
One case of 45,X abortus with high CA 125 level (Check). 1990;163:1717 (Letter)
Postmortem chorionic villus sampling is a better method for cytogenetic evaluation of early fetal loss than culture of abortus material (Johnson et al). 1990;163:1505-10
Prediction of residual trophoblastic tissue in first-trimester abortions: the role of transvaginal Doppler ultrasonography (Reuwen). 1990;163:2024-5 (Letter)
Pregnancy loss terminology (Branch and Scott) (Letter); (Pridjian and Moawad) (Reply). 1990;163:245-6
A progesterone-induced blocking factor corrects high resorption rates in mice treated with antiprogesterone (Szekeres-Bartho et al). 1990;163:1320-1
Recurrent adverse pregnancy outcome and antiphospholipid antibodies (Reece et al). 1990;163:162-9 (Curr. dev.)
Abortion, habitual
Antinuclear antibodies in sera of patients with recurrent pregnancy wastage (Xu et al). 1990;163:1493-7
Immunoglobulin G fractions from patients with antiphospholipid antibodies cause fetal death in BALB/c mice: a model for autoimmune fetal loss (Branch et al). 1990;163:210-6
Serum levels of interleukin-2 and tumor necrosis factor α in women with recurrent abortion (Mallmann et al). 1990;163:1367 (Letter)
Sharing of human leukocyte antigens in primary and secondary recurrent spontaneous abortions (Ho et al). 1990;163:178-88
Abortion, induced
Morphologic study of changes of collagenous tissue in the amnion and cervix during prostaglandin-induced abortion and delivery (Manabe and Yoshida). 1990;163:52-6

*July, part 1, 1-272; part 2, 273-446; August, 447-714; September, 715-1108; October, part 1, 1109-1378; part 2, 1379-1420; November, part 1, 1421-1718; part 2, 1719-1770; December, part 1, 1771-2112; part 2, 2113-218.

Abortion, legal
A chill wind blows: Webster, obstetrics, and the health of women (Chavkin and Rosenfield). 1990;163:450-2 (Clin. opinion)
Abortion, missed
Early pregnancy failure—appropriate terminology (Goldstein). 1990;163:1093 (Letter)
Pregnancy loss terminology (Branch and Scott) (Letter); (Pridjian and Mcawad) (Reply). 1990;163:245-6
Abortion, threatened
A case of Rh isoimmunization: Should threatened first-trimester abortion be an indication for Rh immune globulin prophylaxis? (Dayton et al). 1990;163:63-4
Accelerated fetal growth; *see* **Macrosomia**
Access, venous; *see* **Catheters, indwelling**
Acid-base equilibrium
A comparison of the effect of epidural, general, and no anesthesia on funic acid-base values by stage of labor and type of delivery (Shyken et al). 1990;163:802-7
Comparison of umbilical artery pH and 5-minute Apgar score in the low-birth-weight and very-low-birth-weight infant (Stark et al). 1990;163:818-23
Acidemia, fetal; *see* **Fetal distress**
Acidosis, animal
Does the umbilical artery systolic/diastolic ratio reflect flow or acidosis? (Copel et al). 1990;163:751-6
Hypoxic acidemia, hyperviscosity, and maternal hypertension do not affect the umbilical arterial velocity waveform in fetal sheep (Morrow et al). 1990;163:1313-20
Acidosis, diabetic
Diabetic ketoacidosis and insulin resistance with subcutaneous terbutaline infusion: a case report (Tibaldi et al). 1990;163:509-10
Acoustic stimulation
The intrauterine sound environment of the human fetus during labor (Benzaquen et al). 1990;163:484-90
Vibroacoustic stimulation and fetal behavioral state in normal term human pregnancy (Devoe et al). 1990;163:1156-61
Acquired immunodeficiency syndrome
Transplacental transfer of zidovudine in the near-term pregnant baboon (Hankins et al). 1990;163:728-32
Acromegaly
Acromegaly first diagnosed in pregnancy: the role of bromocriptine therapy (Yap et al). 1990;163:477-8
Activated partial thromboplastin time; *see* **Partial thromboplastin time**
Adenocarcinoma
Colon cancer in pregnancy with elevated maternal serum α-fetoprotein level at presentation (Gonsoulin et al). 1990;163:1172-3
Adenomyosis; *see* **Endometriosis**
Adenosine cyclic monophosphate
Inhibition of aromatase activity by 8-bromo-cyclic adenosine monophosphate in cultured first-trimester human trophoblast (Rodway et al). 1990;163:1546-51
Adhesions
Ultrasonography's role in detection of intrauterine synechiae (Stephens) (Letter); (Valle and Sciarra) (Reply). 1990;163:1106-7
Adhesions, animal
Adhesion formation after ovarian wound repair in New Zealand white rabbits: a comparison of ovarian microsurgical closure with ovarian nonclosure (Wiskind et al). 1990;163:1674-8
Adjuvants, immunologic
A progesterone-induced blocking factor corrects high resorption rates in mice treated with antiprogesterone (Szekeres-Bartho et al). 1990;163:1320-1
Adnexal diseases
Management of selected cystic adnexal masses in postmenopausal women by operative laparoscopy: a pilot study (Parker and Berek). 1990;163:1574-7
Adnexitis
Clindamycin dosage scheduling for acute pelvic infection (Chatwani et al). 1990;163:240 (Letter)
Sexually transmitted diseases and human immunodeficiency virus infection among women with pelvic inflammatory disease (Hoegsberg et al). 1990;163:1135-9
Adrenal cortex hormones
Dose response of thyrotropin-releasing hormone on pulmonary maturation in corticosteroid-treated preterm rabbits (Tabor et al). 1990;163:669-76
Adrenergic agents; *see* **Sympathomimetics**
Adrenergic alpha receptor agonists
Effects of clonidine on breathing movements and electrocortical activity in the fetal lamb (Bamford et al). 1990;163:661-8
Adrenergic beta receptor blockaders
β-Adrenergic receptor blockade in the management of pregnant women with mitral stenosis (Al Kasab et al). 1990;163:37-40
Adrenocorticotropic hormone
The effect of adrenocorticotropic hormone infusion on subsequent pituitary response in the sheep fetus (Cuthrell et al). 1990;163:170-4
Mechanism of action of interleukin-1β in increasing corticotropin-releasing factor and adrenocorticotropin hormone release from cultured human placental cells (Petraglia et al). 1990;163:1307-12
Aerobic exercise; *see* **Exercise**
Aged
Prevalence and determinants of estrogen replacement therapy in elderly women (Cauley et al). 1990;163:1438-44
Aging
Parameters of hypothalamic aging (Seifer and Jones) (Letter); (Alexander and Aksel) (Reply). 1990;163:1715
Air embolism; *see* **Embolism, air**
Alcoholism
Use of the T-ACE questions to detect risk-drinking (Elliot) (Letter); (Sokol) (Reply). 1990;163:684-5
Alkaline phosphatase
Pregnancy-induced hypertension and acute fatty liver of pregnancy: atypical presentations (Brown et al). 1990;163:1154-6
Alpha fetoproteins
Colon cancer in pregnancy with elevated maternal serum α-fetoprotein level at presentation (Gonsoulin et al). 1990;163:1172-3
The effect of adjusting maternal serum α-fetoprotein levels for maternal weight in pregnancies with fetal open spina bifida (Johnson et al). 1990;163:9-11
Maternal serum α-fetoprotein levels in pregnancies complicated by diabetes: implications for screening programs (Martin et al). 1990;163:1209-16
Maternal serum Down syndrome screening: free β-protein is a more effective marker than human chorionic gonadotropin (Macri et al). 1990;163:1248-53
Maternal serum α-fetoprotein in pregnancy (Gilchrist et al) (Letter); (Milunsky et al) (Reply). 1990;163:692-3

Alpha fetoproteins—cont'd
Maternal serum α-fetoprotein level useful screening test (Lao). 1990;163:240 (Letter)
The relationship between maternal serum and amniotic fluid α-fetoprotein in women undergoing early amniocentesis (Brumfield et al). 1990;163:903-6
Should amniocenteses always accompany unexplained high maternal serum α-fetoprotein levels? Who decides: public agency, patient, or private physician? (Stephens) (Letter); (Hogge et al) (Reply). 1990;163:697-8
Ultrasonographic diagnosis of a large placental intervillous thrombosis associated with elevated maternal serum α-fetoprotein level (Jauniaux et al). 1990;163:1558-60
Alprostadil
Venous and hepatic vascular responses to indomethacin and prostaglandin E_1 in the fetal lamb (Paulick et al). 1990;163:1357-63
Ambulatory care
Outpatient obstetric management of women with type I diabetes (Bourgeois and Duffer). 1990;163:1065-73
Amenorrhea
Autogenic masculinization (Punch and Ansbacher). 1990;163:114-6
Efficacy and safety of intravenous pulsatile gonadotropin-releasing hormone: Lutrepulse for injection (Santoro). 1990;163:1759-64 (Supplement)
Hypothalamic amenorrhea: clinical perspectives, pathophysiology, and management (Liu). 1990;163:1732-6 (Supplement)
Practical aspects of pulsatile gonadotropin-releasing hormone administration (Schriock). 1990;163:1765-70 (Supplement)
American Journal of Obstetrics and Diseases of Women and Children
The first seventy years. 1990;163:1109-10 (Editorial)
American Journal of Obstetrics and Gynecology
The first seventy years. 1990;163:1109-10 (Editorial)
Aminobutyric acids
Zinc, preeclampsia, and γ-aminobutyric acid (Brophy). 1990;163:242-3 (Letter)
Aminoglycoside, toxicity
Cefotetan and the lack of associated bleeding (Martens and Faro) (Letter); (Briggs et al) (Reply). 1990;163:251-2
Amniocentesis; *see also* **Amniotic fluid**
Absence of evidence of pulmonary maturity at amniocentesis in term infants of diabetic mothers (Ojomo and Coustan). 1990;163:954-7
Antenatal diagnosis of molybdenum cofactor deficiency (George et al). 1990;163:1203-4
Detection of congenital toxoplasmosis by chorionic villus sampling and early amniocentesis (Foulon et al). 1990;163:1511-3
The diagnostic values of concurrent nonstress testing, amniotic fluid measurement, and Doppler velocimetry in screening a general high-risk population (Devoe et al). 1990;163:1040-8
Effect of maternal-fetal movement on concentration of cells obtained at genetic amniocentesis (Carlan et al). 1990;163:490-3
Gram stain results from amniocentesis in patients with preterm permature rupture of membranes—comparison of maternal and fetal characteristics (Asrat et al). 1990;163:887-9
Intraamniotic infection in the very early phase of the second trimester (Goldstein et al). 1990;163:1261-3
Intrauterine *Listeria* infection: prenatal diagnosis by biophysical assessment and amniocentesis (Liner). 1990;163:1596-7
Postmortem chorionic villus sampling is a better method for cytogenetic evaluation of early fetal loss than culture of abortus material (Johnson et al). 1990;163:1505-10
The relationship between maternal serum and amniotic fluid α-fetoprotein in women undergoing early amniocentesis (Brumfield et al). 1990;163:903-6
Should amniocenteses always accompany unexplained high maternal serum α-fetoprotein levels? Who decides: public agency, patient, or private physician? (Stephens) (Letter); (Hogge et al) (Reply). 1990;163:697-8
The stuck twin phenomenon: Ultrasonographic findings, pregnancy outcome, and management with serial amniocenteses (Mahony et al). 1990;163:1513-22
Transcervical chorionic villus sampling and amniocentesis: a comparison of reliability, culture findings, and fetal outcome (Ferguson et al). 1990;163:926-31
Amnioinfusion; *see* **Amniotic fluid**
Amnion
Evidence of a role for protein kinase C in epidermal growth factor–induced prostaglandin E_2 synthesis in amnion cells (Kniss et al). 1990;163:1883-90
Morphologic study of changes of collagenous tissue in the amnion and cervix during prostaglandin-induced abortion and delivery (Manabe and Yoshida). 1990;163:52-6
Amniotic fluid; *see also* **Amniocentesis**
Amnioinfusion and prevention of meconium aspiration syndrome (Falciglia) (Letter); (Sadovsky and Amon) (Reply). 1990;163:258-9
Amniotic fluid glucose concentration: a rapid and simple method for the detection of intraamniotic infection in preterm labor (Romero et al). 1990;163:968-74
Amniotic fluid midtrimester delta optical density measurements at 450 nm in Rh disease (Nelson) (Letter); (Queenan) (Reply). 1990;163:710-2
Comparisons of glycosylated and nonglycosylated amniotic fluid prolactins in normal second- and third-trimester pregnancies (McCoshen et al). 1990;163:81-5
Corticotropin-releasing hormone in amniotic fluid (Laatikainen) (Letter); (Sasaki) (Reply). 1990;163:1102-3
Dehydration-induced oligohydramnios (Ross) (Letter); (Sherer et al) (Reply). 1990;163:1091-2
Detection of fetal blood contamination by amniotic fluid obtained during cordocentesis (Lazebnik et al). 1990;163:78-80
Does prophylactic amnioinfusion make a difference? (Chauhan) (Letter); (Strong et al) (Reply). 1990;163:1370-1
Ductus arteriosus flow velocity modulation by fetal breathing movements as a measure of fetal lung development (van Eyck et al). 1990;163:558-66
The effect of amnioinfusion on uterine pressure and activity: a preliminary report (Posner et al). 1990;163:813-8
In vitro inhibition of esterase activity in amniotic fluid: comparison with bacterial cultures (Hoskins et al). 1990;163:1944-7
Infants of diabetic mothers with accelerated fetal growth by ultrasonography: Are they all alike? (Keller et al). 1990;163:893-7
Infection and labor. VI. Prevalence, microbiology, and clinical significance of intraamniotic infection in twin gestations with preterm labor (Romero et al). 1990;163:757-61
Intraamniotic infection in the very early phase of the second trimester (Goldstein et al). 1990;163:1261-3

Normal amniotic pressure in oligohydramnios after preterm rupture of membranes (Johnson and Maxwell) (Letter); (Nicolini et al) (Reply). 1990;163:1103-4
Observations on the cause of oligohydramnios in prolonged pregnancy (Trimmer et al). 1990;163:1900-3
Perinatal survival with expectant management of midtrimester rupture of membranes (Major and Kitzmiller). 1990;163:838-44
Prenatal diagnosis of congenital cytomegalovirus infection by virus isolation from amniotic fluid (Weiner and Grose). 1990;163:1253-5
Preterm delivery: a risk factor for retained placenta (Romero et al). 1990;163:823-5
The relationship between maternal serum and amniotic fluid α-fetoprotein in women undergoing early amniocentesis (Brumfield et al). 1990;163:903-6
Risk factors for perinatal group B streptococcal disease after amniotic fluid colonization (Silver et al). 1990;163:19-25
The stuck twin phenomenon: Ultrasonographic findings, pregnancy outcome, and management with serial amniocenteses (Mahony et al). 1990;163:1513-22
Superiority of the four-quadrant sum over the single-deepest-pocket technique in ultrasonographic identification of abnormal amniotic fluid volumes (Moore). 1990;163:762-7

Amniotic fluid embolism; *see* **Embolism, amniotic fluid**

Amphetamines
The perinatal impact of cocaine, amphetamine, and opiate use detected by universal intrapartum screening (Gillogley et al). 1990;163:1535-42
Prevalence of use of cocaine and other substances in an obstetric population (Matera et al). 1990;163:797-801

Analgesia, epidural
Epidural analgesia and cesarean section for dystocia (Chestnut) (Letter); (Thorp and Parisi) (Reply). 1990;163:247-9
Labor epidural analgesia and dystocia-related cesarean section (Downing and Knape). 1990;163:1096-7 (Letter)
The local anesthetic dose is an important issue in evaluation of effects of epidural analgesia in nulliparous women (Puppa et al) (Letter); (Thorp) (Reply). 1990;163:701-3

Androgens
Discrepancy in the diagnoses of hydatidiform mole by macroscopic and microscopic findings and the deoxyribonucleic acid fingerprint method (Takahashi et al). 1990;163:112-3

Anemia
Is intrauterine transfusion associated with diminished fetal growth? (Utter et al). 1990;163:1781-4

Anemia, sickle cell
Liver histopathologic findings in women with sickle cell disease given prophylactic transfusion during pregnancy (Yeomans et al). 1990;163:958-64

Anencephaly
Anencephalics as organ donors (Van Assche). 1990;163:599-600

Anesthesia
Can anesthetic-related maternal mortality be reduced? (Conklin). 1990;163:253-4 (Letter)
A comparison of the effect of epidural, general, and no anesthesia on funic acid-base values by stage of labor and type of delivery (Shyken et al). 1990;163:802-7
Effect of uterine contractility and maternal hypotension on prolonged decelerations after bupivacaine epidural anesthesia (Steiger and Nageotte). 1990;163:808-12
Effectiveness of 1% lidocaine dorsal penile nerve block in infant circumcision (Arnett et al). 1990;163:1074-80

Aneuploidy
Correlation of the testicular determinant factor sequence zinc finger Y with varying gonadal phenotypes in a series of 13 subjects with gonadal dysgenesis because of Y aneuploidy (Tho et al). 1990;163:1968-75

Aneurysm, cerebral; *see* **Cerebral aneurysm**

Angiomatosis
Systemic cystic angiomatosis in pregnancy: a case presentation and review of the literature (Bardeguez et al). 1990;163:42-5

Angiotensin
Low-dose aspirin. II. Relationship of angiotensin II pressor responses, circulating eicosanoids, and pregnancy outcome (Brown et al). 1990;163:1853-61

Angiotensin binding sites; *see* **Receptors, angiotensin**

Anorexia nervosa
Infertility and eating disorders (Stewart et al). 1990;163:1196-9

Anoxia
The effect of maternal hyperoxia on behavioral activity in growth-retarded human fetuses (Gagnon et al). 1990;163:1894-9

Antibiotics
Antibiotic therapy in preterm premature rupture of membranes: a randomized, prospective, double-blind trial (Johnston et al). 1990;163:743-7
Cervicovaginal microflora and pregnancy outcome: results of a double-blind, placebo-controlled trial of erythromycin treatment (McGregor et al). 1990;163:1580-91
Placental transfer of cefazolin and piperacillin in pregnancies remote from term complicated by Rh isoimmunization (Brown et al). 1990;163:938-43

Antibodies
Antiphospholipid antibodies and recurrent pregnancy loss: correlation between the activated partial thromboplastin time and antibodies against phosphatidylserine and cardiolipin (Rote et al). 1990;163:575-84
Autologous antibodies eluted from membrane fragments in human ovarian epithelial neoplastic effusions. III. Cytotoxic potential in vitro and characterization of antigen(s) (Kutteh et al). 1990;163:1301-6
A comparison of sperm antibody assays (Daru and Mathur). 1990;163:1622-9

Antibodies, antinuclear
Antinuclear antibodies in sera of patients with recurrent pregnancy wastage (Xu et al). 1990;163:1493-7

Antibodies, monoclonal
Epithelial cells from normal human endometrium express a tumor-associated glycoprotein (TAG-72) epitope in vitro (Osteen et al). 1990;163:479-84

Antibody formation
Antisperm antibodies in women undergoing intrauterine insemination (Goldberg et al). 1990;163:65-8
Digoxin-like immunoreactive factor and respiratory distress syndrome (Goodlin). 1990;163:1091 (Letter)
Recurrent adverse pregnancy outcome and antiphospholipid antibodies (Reece et al). 1990;163:162-9 (Curr. dev.)

Antibody formation, animal
Immunoglobulin G fractions from patients with antiphospholipid antibodies cause fetal death in BALB/c mice: a

Antibody formation, animal—cont'd
model for autoimmune fetal loss (Branch et al). 1990;163:210-6
Anticardiolipin antibody; *see* **Cardiolipins**
Antiestrogens; *see* **Estrogen antagonists**
Antigenic determinants
Epithelial cells from normal human endometrium express a tumor-associated glycoprotein (TAG-72) epitope in vitro (Osteen et al). 1990;163:479-84
Antigens
A comparison of sperm antibody assays (Daru and Mathur). 1990;163:1622-9
Lymphocyte proliferative response to fertilization antigen in patients with antisperm antibodies (Naz et al). 1990;163:610-3
Antigens, neoplasm
Autologous antibodies eluted from membrane fragments in human ovarian epithelial neoplastic effusions. III. Cytotoxic potential in vitro and characterization of antigen(s) (Kutteh et al). 1990;163:1301-6
Flow cytometric quantitation of tumor-associated antigens in solid tumors (van Dam et al) (Letter); (Nozawa) (Reply). 1990;163:698-9
Antigens, tumor-associated, carbohydrate
Distribution of CA 125 in embryonic tissues and adult derivatives of the fetal periderm (Hardardottir et al). 1990;163:1925-31
One case of 45,X abortus with high CA 125 level (Check). 1990;163:1717 (Letter)
Preoperative evaluation of serum CA 125, TAG 72, and CA 15-3 in patients with endometrial carcinoma (Soper et al). 1990;163:1204-9
The prognostic significance of CA 125 half-life in patients with ovarian cancer who have received primary chemotherapy after surgical cytoreduction (Hunter et al). 1990;163:1164-7
The use of serial CA 125 concentrations to monitor endometriosis in infertile women (Pittaway). 1990;163:1032-7
Antihypertensive agents
National High Blood Pressure Education Program Working Group report on high blood pressure in pregnancy. 1990;163:1691-712 (Supplement)
Antineoplastic agents
Expression of P-glycoprotein in epithelial ovarian cancer: evaluation as a marker of multidrug resistance (Rubin et al). 1990;163:69-73
Antinuclear antibodies; *see* **Antibodies, antinuclear**
Antioxidants
Smoking and the antioxidant ascorbic acid: plasma, leukocyte, and cervicovaginal cell concentrations in normal healthy women (Basu et al). 1990;163:1948-52
Antiphosphatidylserine antibody; *see* **Phosphatidylserines**
Antiphospholipid antibodies; *see* **Phospholipids**
Antiprogesterone; *see* **Mifepristone**
Antiprogesterone, animal; *see* **Receptors, progesterone, animal**
Antisperm antibodies; *see* **Spermatozoa**
Antithrombin III, deficiency
Emergency treatment with recombinant tissue plasminogen activator of pulmonary embolism in a pregnant woman with antithrombin III deficiency (Baudo et al). 1990;163:1274-5
Aorta, descending; *see* **Aorta, thoracic**
Aorta, thoracic
Blood flow velocity and pulsatile diameter changes in the fetal descending aorta: a longitudinal study (Stale et al). 1990;163:26-9
Apgar score
Comparison of umbilical artery pH and 5-minute Apgar score in the low-birth-weight and very-low-birth-weight infant (Stark et al). 1990;163:818-23
Apocrine glands
Distribution of CA 125 in embryonic tissues and adult derivatives of the fetal periderm (Hardardottir et al). 1990;163:1925-31
Argipressin
Role of vasopressin in mediation of fetal cardiovascular responses to acute hypoxia (Piacquadio et al). 1990;163:1294-300
Aromatase
Inhibition of aromatase activity by 8-bromo-cyclic adenosine monophosphate in cultured first-trimester human trophoblast (Rodway et al). 1990;163:1546-51
Arteriovenous fistula
In utero detection of cardiac failure from an aneurysm of the vein of Galen (Jeanty et al). 1990;163:50-1
Ascites, fetal
Antenatal spontaneous perforation of the extrahepatic biliary tree (Chilukuri et al). 1990;163:1201-2
Ascorbic acid
Smoking and the antioxidant ascorbic acid: plasma, leukocyte, and cervicovaginal cell concentrations in normal healthy women (Basu et al). 1990;163:1948-52
Asphyxia, fetal; *see* **Fetal anoxia**
Asphyxia neonatorum
What is birth asphyxia? (Clark and Quirk) (Letter); (Thorp) (Reply). 1990;163:1367-8
Aspirin
Low-dose aspirin. II. Relationship of angiotensin II pressor responses, circulating eicosanoids, and pregnancy outcome (Brown et al). 1990;163:1853-61
National High Blood Pressure Education Program Working Group report on high blood pressure in pregnancy. 1990;163:1691-712 (Supplement)
Atherosclerosis
Effects of oral contraceptives on lipid metabolism (Gevers Leuven et al). 1990;163:1410-3 (Supplement)
Oral contraceptives, lipoproteins, and atherosclerosis (Adams et al). 1990;163:1388-92 (Supplement)
Role of plasma lipoproteins in the pathogenesis of atherosclerotic disease, with special reference to sex hormone effects (Tikkanen). 1990;163:296-304 (Supplement)
Atrial natriuretic factor; *see* **Natriuretic peptides, atrial**
Autoantibodies
Association between autoantibodies and unexplained infertility unproved (Maier) (Letter); (Taylor and Campbell) (Reply). 1990;163:243
Autogenic masculinization; *see* **Self medication**
Autoimmune diseases
Antiphospholipid antibodies and recurrent pregnancy loss: correlation between the activated partial thromboplastin time and antibodies against phosphatidylserine and cardiolipin (Rote et al). 1990;163:575-84
Autoimmunity, animal
Immunoglobulin G fractions from patients with antiphospholipid antibodies cause fetal death in BALB/c mice: a model for autoimmune fetal loss (Branch et al). 1990;163:210-6

Autologous blood transfusion; *see* **Blood transfusion, autologous**
Automatic data processing
Blood pressure measured telemetrically from home throughout pregnancy (Mooney et al). 1990;163:30-6

B

Bacterial infections
Antenatal microbiologic and maternal risk factors associated with prematurity (McGregor et al). 1990;163:1465-73
Bacterial vaginosis: diagnostic and pathogenetic findings during topical clindamycin therapy (Livengood et al). 1990;163:515-20
Cervicovaginal microflora and pregnancy outcome: results of a double-blind, placebo-controlled trial of erythromycin treatment (McGregor et al). 1990;163:1580-91
A follow-up study of methods of contraception, sexual activity, and rates of trichomoniasis, candidiasis, and bacterial vaginosis (Barbone et al). 1990;163:510-4
In vitro inhibition of esterase activity in amniotic fluid: comparison with bacterial cultures (Hoskins et al). 1990;163:1944-7
Bacterial infections, animal
A rabbit model for bacteria-induced preterm pregnancy loss (Dombroski et al). 1990;163:1938-43
Behavior, fetus
Human fetal foramen ovale flow velocity waveforms relative to behavioral states in normal term pregnancy (van Eyck et al). 1990;163:1239-42
Vibroacoustic stimulation and fetal behavioral state in normal term human pregnancy (Devoe et al). 1990;163:1156-61
Behavior, infant
The association of intrapartum asphyxia in the mature fetus with newborn behavior (Low et al). 1990;163:1131-5
Correlations between antepartum maternal metabolism and newborn behavior (Rizzo et al). 1990;163:1458-64
Beta-adrenergic receptor blockaders; *see* **Adrenergic beta receptor blockaders**
17β-estradiol; *see* **Estradiol**
Bias
Ascertainment bias in diabetic outcome data (FitzSimmons and Davidson) (Letter); (Damm and Mølsted-Pedersen) (Reply). 1990;163:682-3
Biliary tract
Antenatal spontaneous perforation of the extrahepatic biliary tree (Chilukuri et al). 1990;163:1201-2
Biophysical assessment; *see* **Fetal monitoring**
Biopsy
Preembryo biopsy and analysis of blastomeres by in situ hybridization (Grifo et al). 1990;163:2013-9
Preventing cervical conization by achieving satisfactory colposcopy with hygroscopic cervical dilators (Stern et al). 1990;163:176-7
Second-trimester placental biopsy for rapid fetal karyotyping (Cameron et al). 1990;163:931-4
Birth weight
The effect of physical activity during pregnancy on preterm delivery and birth weight (Klebanoff et al). 1990;163:1450-6
The effect of race on the relationship between fetal death and altered fetal growth (Ferguson and Myers). 1990;163:1222-30
Neonatal morphometrics after endurance exercise during pregnancy (Clapp and Capeless). 1990;163:1805-11
Prognosis for twins with birth weight <1500 gm: the impact of cesarean section in relation to fetal presentation (Rydhström). 1990;163:528-33
Ultrasonographic fetal weight estimation by an integrated computer-assisted system: Can each laboratory improve its accuracy? (Thompson et al). 1990;163:986-95
Bladder
The effect of large uterine fibroids on urinary bladder function symptoms (Langer et al). 1990;163:1139-41
Blastomeres
Preembryo biopsy and analysis of blastomeres by in situ hybridization (Grifo et al). 1990;163:2013-9
Bleeding, first-trimester; *see* **Abortion, threatened**
Blood, radiation effects
Hyperkalemia secondary to irradiation of packed red blood cells: possible effects with intravascular fetal transfusion (Thorp et al). 1990;163:607-9
Blood coagulation
Clinical aspects of the relationship between oral contraceptives and abnormalities of the hemostatic system: relation to the development of cardiovascular disease (Kelleher). 1990;163:392-5 (Supplement)
Comparative studies of 30 μg ethinyl estradiol combined with gestodene and desogestrel on blood coagulation, fibrinolysis, and platelets (Daly and Bonnar). 1990;163:430-7 (Supplement)
Disorders of the hemostatic system and the risk of the development of thrombotic and cardiovascular diseases: limitations of laboratory diagnosis (Kluft). 1990;163:305-12 (Supplement)
Effects of long-term gestodene-containing oral contraceptive administration on hemostasis (Abbate et al). 1990;163:424-9 (Supplement)
Effects of newer oral contraceptives on the inhibition of coagulation and fibrinolysis in relation to dosage and type of steroid (Jespersen et al). 1990;163:396-403 (Supplement)
Enhanced generation and resolution of fibrin in women above the age of 30 years using oral contraceptives low in estrogen (Gram et al). 1990;163:438-42 (Supplement)
Hemostasis profile in women taking low-dose oral contraceptives (David et al). 1990;163:420-3 (Supplement)
Influence of oral contraceptives on coagulation tests in native blood and plasma (Kunz et al). 1990;163:417-20 (Supplement)
Metabolic changes during the normal menstrual cycle: a longitudinal study (Lebech et al). 1990;163:414-6 (Supplement)
Metabolic changes during treatment with two different progestogens (Refn et al). 1990;163:374-7 (Supplement)
Blood coagulation disorders
Disorders of the hemostatic system and the risk of the development of thrombotic and cardiovascular diseases: limitations of laboratory diagnosis (Kluft). 1990;163:305-12 (Supplement)
Blood flow velocity
Blood flow velocity and pulsatile diameter changes in the fetal descending aorta: a longitudinal study (Stale et al). 1990;163:26-9
Human fetal foramen ovale flow velocity waveforms relative to behavioral states in normal term pregnancy (van Eyck et al). 1990;163:1239-42
Blood gas analysis
Relationship of fetal biophysical profile and blood gas values

Blood gas analysis—cont'd
at cordocentesis in severely growth-retarded fetuses (Ribbert et al). 1990;163:569-71
Blood platelet disorders
Responsibility expands to extended family members (Saving et al). 1990;163:1369-70 (Letter)
Blood platelets
Changes in platelet angiotensin II binding sites associated with the human menstrual cycle (Baker et al). 1990;163:175-6
Comparative studies of 30 μg ethinyl estradiol combined with gestodene and desogestrel on blood coagulation, fibrinolysis, and platelets (Daly and Bonnar). 1990;163:430-7 (Supplement)
Cordocentesis and immune thrombocytopenia—continued (Weiner). 1990;163:1371-2 (Letter)
Hemostasis profile in women taking low-dose oral contraceptives (David et al). 1990;163:420-3 (Supplement)
Blood pressure
Fetal umbilical artery Doppler response to graded maternal aerobic exercise and subsequent maternal mean arterial blood pressure: predictive value for pregnancy-induced hypertension (Hume et al). 1990;163:826-9
Low-dose aspirin. II. Relationship of angiotensin II pressor responses, circulating eicosanoids, and pregnancy outcome (Brown et al). 1990;163:1853-61
Blood pressure, animal
Does the umbilical artery systolic/diastolic ratio reflect flow or acidosis? (Copel et al). 1990;163:751-6
Blood pressure determination
Blood pressure measured telemetrically from home throughout pregnancy (Mooney et al). 1990;163:30-6
Blood transfusion
Liver histopathologic findings in women with sickle cell disease given prophylactic transfusion during pregnancy (Yeomans et al). 1990;163:958-64
Blood transfusion, autologous
A reappraisal of the need for autologous blood donation in the obstetric patient (Andres et al). 1990;163:1551-3
Blood transfusion, intrauterine
Acute fetal hemodynamic alterations after intrauterine transfusion for treatment of severe red cell alloimmunization (Moise et al). 1990;163:776-84
Continuing controversy in alloimmune thrombocytopenia: fetal hyperimmunoglobulinemia fails to prevent thrombocytopenia (Nicolini et al). 1990;163:1144-6
Effects of intravascular fetal blood transfusion on fetal intracardiac Doppler velocity waveforms (Rizzo et al). 1990;163:1231-8
Hyperkalemia secondary to irradiation of packed red blood cells: possible effects with intravascular fetal transfusion (Thorp et al). 1990;163:607-9
Is intrauterine transfusion associated with diminished fetal growth? (Utter et al). 1990;163:1781-4
Blood viscosity, animal
Hypoxic acidemia, hyperviscosity, and maternal hypertension do not affect the umbilical arterial velocity waveform in fetal sheep (Morrow et al). 1990;163:1313-20
Blood volume
Interrelationship between atrial natriuretic factor concentrations and acute volume expansion in pregnant and nonpregnant women (Hatjis et al). 1990;163:45-50
Body habitus; *see* **Body mass index**
Body mass index
Glucose tolerance in pregnancy: ethnic variation and influence of body habitus (Green et al). 1990;163:86-92
Body weight
The effect of adjusting maternal serum α-fetoprotein levels for maternal weight in pregnancies with fetal open spina bifida (Johnson et al). 1990;163:9-11
Bone density
The relationship between plasma estradiol and the increase in bone density in postmenopausal women after treatment with subcutaneous hormone implants (Studd et al). 1990;163:1474-9
Bone loss, age-related; *see* **Osteoporosis**
Books
Books received. 1990;163:713, 2031
Brain
Assessment of cerebral hemodynamics in pregnant women by internal carotid artery pulsed Doppler velocimetry (Ikeda and Mori). 1990;163:494-8
Long-term maternal-fetal exposure to high-low insulin concentrations alter liver but not brain insulin receptors (Devaskar et al). 1990;163:1350-6
Breakthrough bleeding; *see* **Uterine hemorrhage**
Breast diseases
Breast diagnostics in clinical gynecology (Cross) (Letter); (Gleicher) (Reply). 1990;163:686-7
Breast disease programs and mammography training (Dodd and McLelland) (Letter); (Gleicher) (Reply). 1990;163:689-91
Breast milk; *see* **Milk, human**
Breast neoplasms
Oral contraceptives and breast cancer (Schlesselman). 1990;163:1379-87 (Supplement)
Prevalence and determinants of estrogen replacement therapy in elderly women (Cauley et al). 1990;163:1438-44
Breech presentation
Pelvimetry by magnetic resonance imaging in breech presentation (van Loon et al). 1990;163:1256-60
Vaginal breech delivery: a five-year prospective evaluation of a protocol using computed tomographic pelvimetry (Christian et al). 1990;163:848-55
Broad ligament
Papillary cystadenoma of the broad ligament in von Hippel-Lindau disease (Korn et al). 1990;163:596-8
Bromocriptine
Acromegaly first diagnosed in pregnancy: the role of bromocriptine therapy (Yap et al). 1990;163:477-8
Bulimia
Infertility and eating disorders (Stewart et al). 1990;163:1196-9
Bupivacaine
Effect of uterine contractility and maternal hypotension on prolonged decelerations after bupivacaine epidural anesthesia (Steiger and Nageotte). 1990;163:808-12

C

CA 15-3; *see* **Antigens, tumor-associated, carbohydrate**
CA 125; *see* **Antigens, tumor-associated, carbohydrate**
Calcinosis
Prenatal diagnosis of fetal intracranial calcifications (Koga et al). 1990;163:1543-5
Calcium
Calcium supplementation during pregnancy may reduce preterm delivery in high-risk populations (Villar and Repke). 1990;163:1124-31
National High Blood Pressure Education Program Working Group report on high blood pressure in pregnancy. 1990;163:1691-712 (Supplement)

Relationship between plasma calcium fractions, other bone-related variables, and serum follicle-stimulating hormone levels in premenopausal, perimenopausal, and postmenopausal women (Nordin et al). 1990;163:140-5

Calcium channel blockers

Effects of magnesium and isradipine on contractile activation induced by the thromboxane A_2 analog U46619 in human uteroplacental arteries in term pregnancy (Skajaa et al). 1990;163:1323-33

Candidiasis, vulvovaginal

A follow-up study of methods of contraception, sexual activity, and rates of trichomoniasis, candidiasis, and bacterial vaginosis (Barbone et al). 1990;163:510-4

Captopril

Maternal and uteroplacental hemodynamic effects of chronic captopril in the hypertensive, term-pregnant rat (Mabie et al). 1990;163:1861-7

Carbohydrates, metabolism

Clinical aspects of the relationship between oral contraceptives, abnormalities in carbohydrate metabolism, and the development of cardiovascular disease (Gaspard and Lefebvre). 1990;163:334-43 (Supplement)

Effect of low-dose oral contraceptives on carbohydrate and lipid metabolism in women with recent gestational diabetes: results of a controlled, randomized, prospective study (Kjos et al). 1990;163:1822-7

Effects of oral contraceptives on carbohydrate and lipid metabolisms in a healthy population: the Telecom Study (Simon et al). 1990;163:382-7 (Supplement)

Interrelations between carbohydrates, lipids, and the hemostatic system in relation to the risk of thrombotic and cardiovascular disease (Juhan-Vague and Vague). 1990;163:313-5 (Supplement)

Low-dose oral contraceptives and carbohydrate metabolism (Godsland et al). 1990;163:348-53 (Supplement)

Mechanism of action of oral contraceptives on carbohydrate metabolism at the cellular level (Skouby et al). 1990;163:343-8 (Supplement)

Carbon dioxide laser surgery; *see* **Laser surgery**

Carcinogens; *see also* **Teratogens**

Ovarian granulosa cell tumorigenesis in SWR-derived F1 hybrid mice: preneoplastic follicular abnormality and malignant disease progression (Tennent et al). 1990;163:625-34

Carcinoma

Autologous antibodies eluted from membrane fragments in human ovarian epithelial neoplastic effusions. III. Cytotoxic potential in vitro and characterization of antigen(s) (Kutteh et al). 1990;163:1301-6

Collagen metabolism in gynecologic patients: changes in the concentration of the aminoterminal propeptide of type III procollagen in serum (Puistola et al). 1990;163:1276-81

Invasive carcinoma of the vulva (Cavanagh et al). 1990;163:1007-15

Preoperative evaluation of serum CA 125, TAG 72, and CA 15-3 in patients with endometrial carcinoma (Soper et al). 1990;163:1204-9

Carcinoma, ovarian; *see* **Ovarian neoplasms**

Cardiac output

Acute fetal hemodynamic alterations after intrauterine transfusion for treatment of severe red cell alloimmunization (Moise et al). 1990;163:776-84

Measurement of cardiac output by impedance technique (Easterling and Benedetti). 1990;163:1104-6 (Letter)

Measurement of cardiac output with impedance cardiography (Lechner). 1990;163:1096 (Letter)

Cardiac-placental connection; *see* **Fetal heart**

Cardiography, impedance

Measurement of cardiac output by impedance technique (Easterling and Benedetti). 1990;163:1104-6 (Letter)

Measurement of cardiac output with impedance cardiography (Lechner). 1990;163:1096 (Letter)

Cardiolipins

Antiphospholipid antibodies and recurrent pregnancy loss: correlation between the activated partial thromboplastin time and antibodies against phosphatidylserine and cardiolipin (Rote et al). 1990;163:575-84

Recurrent adverse pregnancy outcome and antiphospholipid antibodies (Reece et al). 1990;163:162-9 (Curr. dev.)

Cardiomyopathy, congestive

Ritodrine infusion and cardiomyopathy (Caritis) (Letter); (Blickstein) (Reply). 1990;163:254-6

Cardiopulmonary bypass

Sinusoidal fetal heart rate pattern during cardiopulmonary bypass (Burke et al). 1990;163:17-8

Successful treatment of postpartum shock caused by amniotic fluid embolism with cardiopulmonary bypass and pulmonary artery thromboembolectomy (Esposito et al). 1990;163:572-4

Cardiovascular complications of pregnancy; *see* **Pregnancy complications, cardiovascular**

Cardiovascular diseases, complications

Clinical aspects of the relationship between oral contraceptives, abnormalities in carbohydrate metabolism, and the development of cardiovascular disease (Gaspard and Lefebvre). 1990;163:334-43 (Supplement)

Clinical aspects of the relationship between oral contraceptives and abnormalities of the hemostatic system: relation to the development of cardiovascular disease (Kelleher). 1990;163:392-5 (Supplement)

Interrelations between carbohydrates, lipids, and the hemostatic system in relation to the risk of thrombotic and cardiovascular disease (Juhan-Vague and Vague). 1990;163:313-5 (Supplement)

Some aspects of the relationship between oral contraceptives, lipid abnormalities, and cardiovascular disease (Samsioe and Mattsson). 1990;163:354-8 (Supplement)

Cardiovascular diseases, diagnosis

Disorders of the hemostatic system and the risk of the development of thrombotic and cardiovascular diseases: limitations of laboratory diagnosis (Kluft). 1990;163:305-12 (Supplement)

Cardiovascular diseases, epidemiology

An epidemiologic survey of cardiovascular disease in women taking oral contraceptives (Thorogood and Vessey). 1990;163:274-81 (Supplement)

Past use of oral contraceptives and cardiovascular disease: a meta-analysis in the context of the Nurses' Health Study (Stampfer et al). 1990;163:285-91 (Supplement)

Cardiovascular diseases, mortality

Cardiovascular death among women under 40 years of age using low-estrogen oral contraceptives and intrauterine devices in Finland from 1975 to 1984 (Hirvonen and Idänpään-Heikkilä). 1990;163:281-4 (Supplement)

Cardiovascular system

Impairment of glucose tolerance: mechanism of action and impact on the cardiovascular system (Beck-Nielsen et al). 1990;163:292-5 (Supplement)

Cardiovascular system, animal
Progesterone increases cardiovascular toxicity to cocaine in nonpregnant ewes (Plessinger and Woods). 1990;163:1659-64
Carotid artery, internal
Assessment of cerebral hemodynamics in pregnant women by internal carotid artery pulsed Doppler velocimetry (Ikeda and Mori). 1990;163:494-8
Carrier state
HBcAg identification in the placental cytotypes of symptom-free HBsAg-carrier mothers: a study with the immunoperoxidase method (Lucifora et al). 1990; 163:235-9
Catechol estrogens
Formation, metabolism, and physiologic importance of catecholestrogens (Ball and Knuppen). 1990;163:2163-70 (Symposium)
Catecholamines
Neuromodulatory regulation of gonadotropin-releasing hormone pulsatile discharge in women (Jaffe et al). 1990;163:1727-31 (Supplement)
Catheterization
Alteration of 24-hour rhythms in myometrial activity in the chronically catheterized pregnant rhesus monkey after a 6-hour shift in the light-dark cycle (Figueroa et al). 1990;163:648-54
Catheters, indwelling
Ultrasonographic guidance for central venous access (Greenspoon) (Letter); (Lee) (Reply). 1990;163: 252
Caucasoid race
The effect of race on the relationship between fetal death and altered fetal growth (Ferguson and Myers). 1990;163:1222-30
Cefazolin
Placental transfer of cefazolin and piperacillin in pregnancies remote from term complicated by Rh isoimmunization (Brown et al). 1990;163:938-43
Cefotetan
Cefotetan and the lack of associated bleeding (Martens and Faro) (Letter); (Briggs et al) (Reply). 1990;163: 251-2
Cell division
Proliferative and antiproliferative effects of interferon-γ and tumor necrosis factor-α on cell lines derived from cervical and ovarian malignancies (Mutch et al). 1990;163:1920-4
Cell growth; *see* **Cell division**
Cell-mediated immunity; *see* **Immunity, cellular**
Cell surface glycoproteins; *see* **Membrane glycoproteins**
Cells, cultured
Comparison of norethindrone and medroxyprogesterone acetate with natural progesterone and estradiol in stimulating prolactin production from cultured endometrial stromal cells (Levin et al). 1990;163: 1932-8
Evidence of a role for protein kinase C in epidermal growth factor–induced prostaglandin E_2 synthesis in amnion cells (Kniss et al). 1990;163:1883-90
Inhibition of aromatase activity by 8-bromo-cyclic adenosine monophosphate in cultured first-trimester human trophoblast (Rodway et al). 1990;163:1546-51
Central venous pressure
Ultrasonographic guidance for central venous access (Greenspoon) (Letter); (Lee) (Reply). 1990;163: 252
Cerclage; *see* **Pregnancy, prolonged**
Cerclage, cervical; *see* **Cervical incompetence**
Cerebral aneurysm
In utero detection of cardiac failure from an aneurysm of the vein of Galen (Jeanty et al). 1990;163:50-1
Cerebral circulation; *see* **Brain**
Cerebral palsy
Cerebral palsy and intrapartum fetal acidemia (Goodlin) (Letter); (Dennis et al) (Reply). 1990;163:266-7
Prognosis for twins with birth weight <1500 gm: the impact of cesarean section in relation to fetal presentation (Rydhström). 1990;163:528-33
Cerebral veins
In utero detection of cardiac failure from an aneurysm of the vein of Galen (Jeanty et al). 1990;163:50-1
Cerebrovascular disorders
Past use of oral contraceptives and cardiovascular disease: a meta-analysis in the context of the Nurses' Health Study (Stampfer et al). 1990;163:285-91 (Supplement)
Cervical cerclage; *see* **Cervical incompetence**
Cervical conization; *see* **Biopsy**
Cervical dilators; *see* **Surgical instruments**
Cervical incompetence
The Shirodkar operation: a reappraisal (Frieden et al). 1990;163:830-3
Cervical pregnancy; *see* **Pregnancy, ectopic**
Cervical ripening; *see* **Cervix uteri**; **Labor, induced**
Cervix mucus
Antisperm antibodies in women undergoing intrauterine insemination (Goldberg et al). 1990;163:65-8
Cervix neoplasms
Cervical cancer: Role for progesterone during pregnancy and contraception? (Stendahl and Rogo). 1990;163:685-6 (Letter)
Proliferative and antiproliferative effects of interferon-γ and tumor necrosis factor-α on cell lines derived from cervical and ovarian malignancies (Mutch et al). 1990;163:1920-4
Smoking and the antioxidant ascorbic acid: plasma, leukocyte, and cervicovaginal cell concentrations in normal healthy women (Basu et al). 1990;163:1948-52
Successful conservative management of primary nonmetastatic cervical choriocarcinoma (Ben-Chetrit et al). 1990;163:1161-3
Trend of cervical cancer in Jewish women (Baruch and Menczer) (Letter); (Glezerman et al) (Reply). 1990;163:703-4
The use of in situ hybridization to show human papillomavirus deoxyribonucleic acid in metastatic cancer cells within lymph nodes (Lewandowski et al). 1990;163:1333-7
Cervix uteri
Conservative management of cervical pregnancy with subsequent fertility (Ayromlooi) (Letter); (Bachus) (Reply). 1990;163:1093-5
Modified laparoscopy for monitoring transcervical surgery (Lin and Iwata). 1990;163:243-4 (Letter)
Morphologic study of changes of collagenous tissue in the amnion and cervix during prostaglandin-induced abortion and delivery (Manabe and Yoshida). 1990; 163:52-6
Prediction of risk for preterm delivery by ultrasonographic measurement of cervical length (Andersen et al). 1990;163:859-67
Preventing cervical conization by achieving satisfactory col-

poscopy with hygroscopic cervical dilators (Stern et al). 1990;163:176-7
Role of hormones in cervical ripening (Sert). 1990;163:705-7 (Letter)

Cervix uteri, animal
Effect of intravaginal application of prostaglandin E_2 gel on the mechanical properties of the ovine cervix uteri at term (Owiny and Fitzpatrick). 1990;163:657-60

Cesarean section
Catastrophic complications of previous cesarean section (Chazotte and Cohen). 1990;163:738-42
Epidural analgesia and cesarean section for dystocia (Chestnut) (Letter); (Thorp and Parisi) (Reply). 1990;163:247-9
Extensive vulvar and vaginal varicella necessitating abdominal delivery (Sites et al). 1990;163:1630-1
Fetal gastroschisis and omphalocele: Is cesarean section the best mode of delivery? (Lewis et al). 1990;163:773-5
Fetal heart rate monitoring during cesarean section (Dunn) (Letter); (Petrikovsky et al) (Reply). 1990;163:253
The incidence of significant fetomaternal hemorrhage in patients undergoing cesarean section (Feldman et al). 1990;163:855-8
Labor epidural analgesia and dystocia-related cesarean section (Downing and Knape). 1990;163:1096-7 (Letter)
Prognosis for twins with birth weight <1500 gm: the impact of cesarean section in relation to fetal presentation (Rydhström). 1990;163:528-33
Reducing cesarean sections at a teaching hospital (Sanchez-Ramos et al). 1990;163:1081-8
Safe motherhood: Cesarean section or symphysiotomy? (van Roosmalen). 1990;163:1-4 (Clin. opinion)
Surgical staples in cesarean section: a randomized controlled trial (Villeneuve et al). 1990;163:1641-6
Ultrasonographic evaluation of uteroplacental blood flow patterns of abnormally located and adherent placentas (Guy et al). 1990;163:723-7
Vaginal birth after abdominal delivery (Thorp and Bowes). 1990;163:1101-2 (Letter)
Vaginal birth after cesarean section: an appraisal of the reappraisal (Flamm) (Letter); (Yetman) (Reply). 1990;163:691-2

Chemotherapy
Expression of P-glycoprotein in epithelial ovarian cancer: evaluation as a marker of multidrug resistance (Rubin et al). 1990;163:69-73

Chest wall; *see* **Thorax**

Chickenpox
Extensive vulvar and vaginal varicella necessitating abdominal delivery (Sites et al). 1990;163:1630-1

Chorioamnionitis
Amniotic fluid glucose concentration: a rapid and simple method for the detection of intraamniotic infection in preterm labor (Romero et al). 1990;163:968-74
In vitro inhibition of esterase activity in amniotic fluid: comparison with bacterial cultures (Hoskins et al). 1990;163:1944-7
Perinatal survival with expectant management of midtrimester rupture of membranes (Major and Kitzmiller). 1990;163:838-44
Preterm delivery: a risk factor for retained placenta (Romero et al). 1990;163:823-5
Secretion of phospholipases by bacterial pathogens may initiate preterm labor (Bennett et al). 1990;163:241-2 (Letter)

Choriocarcinoma
Isolation and characterization of the gene from a human genome encoding 17β-estradiol dehydrogenase: a comparison of Jar and BeWo choriocarcinoma cell lines (Long et al). 1990;163:1976-81
Successful conservative management of primary nonmetastatic cervical choriocarcinoma (Ben-Chetrit et al). 1990;163:1161-3

Chorion
Cases with ruptured membranes that "reseal" (Johnson et al). 1990;163:1024-32
Spontaneous infarction of placental chorioangioma and associated regression of hydrops fetalis (Chazotte et al). 1990;163:1180-1

Chorionic gonadotropins; *see* **Gonadotropins, chorionic**

Chorionic villi sampling
Antenatal diagnosis of molybdenum cofactor deficiency (George et al). 1990;163:1203-4
Detection of congenital toxoplasmosis by chorionic villus sampling and early amniocentesis (Foulon et al). 1990;163:1511-3
Direct analysis of uncultured cytotrophoblastic cells from second- and third-trimester placentas: an accurate and rapid method for detection of fetal chromosome abnormalities (Shulman et al). 1990;163:1606-9
An evaluation of the chorionic villus sampling learning curve (Silver et al). 1990;163:917-22
Postmortem chorionic villus sampling is a better method for cytogenetic evaluation of early fetal loss than culture of abortus material (Johnson et al). 1990;163:1505-10
Second-trimester placental biopsy for rapid fetal karyotyping (Cameron et al). 1990;163:931-4
Transcervical chorionic villus sampling and amniocentesis: a comparison of reliability, culture findings, and fetal outcome (Ferguson et al). 1990;163:926-31

Chromosome abnormalities
The association of single umbilical artery with cytogenetically abnormal pregnancies (Saller et al). 1990;163:922-5
Cytogenetic uncertainties surrounding the fragile X in Martin-Bell syndrome (Sindwani and Verma). 1990;163:1713-4 (Letter)
Direct analysis of uncultured cytotrophoblastic cells from second- and third-trimester placentas: an accurate and rapid method for detection of fetal chromosome abnormalities (Shulman et al). 1990;163:1606-9
Placental histology in fetuses between 18 and 23 weeks' gestation with abnormal karyotype (Kuhlmann et al). 1990;163:1264-70
Ultrasonographic detection of the second-trimester fetus with trisomy 18 and trisomy 21 (Ginsberg et al). 1990;163:1186-90

Chronic renal disease; *see* **Kidney failure, chronic**

Cigarette smoking; *see* **Smoking**

Circadian rhythm
Alteration of 24-hour rhythms in myometrial activity in the chronically catheterized pregnant rhesus monkey after a 6-hour shift in the light-dark cycle (Figueroa et al). 1990;163:648-54

Circumcision
Effectiveness of 1% lidocaine dorsal penile nerve block in infant circumcision (Arnett et al). 1990;163:1074-80

Cisplatin
The prognostic significance of CA 125 half-life in patients with ovarian cancer who have received primary chemo-

Cisplatin—cont'd
therapy after surgical cytoreduction (Hunter et al). 1990;163:1164-7
Clindamycin
Bacterial vaginosis: diagnostic and pathogenetic findings during topical clindamycin therapy (Livengood et al). 1990;163:515-20
Clindamycin dosage scheduling for acute pelvic infection (Chatwani et al). 1990;163:240 (Letter)
Clinical opinion
Clinical opinion. 1990;163:1-8, 447-52, 1111-9, 1421-9
Clinical studies; *see* **Evaluation studies**
Clomiphene
Luteal insufficiency: correlation between endometrial dating and integrated progesterone output in clomiphene citrate–induced cycles (Hecht et al). 1990;163:1986-91
Clonidine
Effects of clonidine on breathing movements and electrocortical activity in the fetal lamb (Bamford et al). 1990;163:661-8
Clostridiopeptidase A
Changes in active and latent collagenase in human placenta around the time of parturition (Rajabi et al). 1990;163:499-503
Closure, surgical; *see* **Surgery, operative**
Cocaine
Cocaine effects on fetal behavioral state (Tabor and Soffici) (Letter); (Hume) (Reply). 1990;163:1364-5
Cocaine-related maternal death (Burkett et al). 1990;163:40-1
Lack of specific placental abnormality associated with cocaine use (Gilbert et al). 1990;163:998-9
Metabolism of cocaine by human placentas: implications for fetal exposure (Roe et al). 1990;163:715-8
The perinatal impact of cocaine, amphetamine, and opiate use detected by universal intrapartum screening (Gillogley et al). 1990;163:1535-42
Prevalence of use of cocaine and other substances in an obstetric population (Matera et al). 1990;163:797-801
Progesterone increases cardiovascular toxicity to cocaine in nonpregnant ewes (Plessinger and Woods). 1990;163:1659-64
The relationship of cocaine use to syphilis and human immunodeficiency virus infections among inner city parturient women (Minkoff et al). 1990;163:521-6
Rupture of unscarred uterus in primigravid woman in association with cocaine abuse (Gonsoulin et al). 1990;163:526-7
Coitus
Hemoperitoneum as a result of coital injury without associated vaginal injury (McColgin et al). 1990;163:1503-5
Collagen
Collagen metabolism in gynecologic patients: changes in the concentration of the aminoterminal propeptide of type III procollagen in serum (Puistola et al). 1990;163:1276-81
Morphologic study of changes of collagenous tissue in the amnion and cervix during prostaglandin-induced abortion and delivery (Manabe and Yoshida). 1990;163:52-6
Collagenase; *see* **Clostridiopeptidase A**
Colonic neoplasms
Colon cancer in pregnancy with elevated maternal serum α-fetoprotein level at presentation (Gonsoulin et al). 1990;163:1172-3
Colony-stimulating factor
Lymphokine production during term human pregnancy: differences between peripheral leukocytes and decidual cells (Dudley et al). 1990;163:1890-3
Color flow Doppler; *see* **Flowmeters**
Colposcopy
Colposcopy in diethylstilbestrol-exposed offspring (Gimbel) (Letter); (Helmerhorst) (Reply). 1990;163:703
Preventing cervical conization by achieving satisfactory colposcopy with hygroscopic cervical dilators (Stern et al). 1990;163:176-7
Combination chemotherapy; *see* **Drug therapy, combination**
Computed tomography; *see* **Tomography, x-ray computed**
Computer-assisted diagnosis; *see* **Diagnosis, computer-assisted**
Conception; *see* **Fertilization**
Congenital abnormalities; *see* **Abnormalities**
Congenital cytomegalovirus infection; *see* **Cytomegaloviruses**
Congenital infection; *see* **Infection, congenital**
Congenital toxoplasmosis; *see* **Toxoplasmosis, congenital**
Consensus development statement
Consensus development statement. 1990;163:1689-712
Consultants
Consultants for the American Journal of Obstetrics and Gynecology, September 1, 1989 — August 31, 1990. 1990;163:1771-80
Contraception
Cervical cancer: Role for progesterone during pregnancy and contraception? (Stendahl and Rogo). 1990;163:685-6 (Letter)
Contraception and ectopic pregnancy risk (Franks et al). 1990;163:1120-3
Contraception, immunologic
Lymphocyte proliferative response to fertilization antigen in patients with antisperm antibodies (Naz et al). 1990;163:610-3
Contraceptives, oral
Binding of oral contraceptive progestogens to serum proteins and cytoplasmic receptor (Juchem and Pollow). 1990;163:2171-83 (Symposium)
Clinical acceptability of monophasic gestodene (Düsterberg and Brill). 1990;163:1398-403 (Supplement)
Effect of low-dose oral contraceptives on carbohydrate and lipid metabolism in women with recent gestational diabetes: results of a controlled, randomized, prospective study (Kjos et al). 1990;163:1822-7
Effects of oral contraceptives on lipid metabolism (Gevers Leuven et al). 1990;163:1410-3 (Supplement)
Factors affecting the enterohepatic circulation of oral contraceptive steroids (Orme and Back). 1990;163:2146-52 (Symposium)
First European Conference on Sex Steroids and Metabolism: introductory remarks (Jespersen et al). 1990;163:273 (Supplement)
A follow-up study of methods of contraception, sexual activity, and rates of trichomoniasis, candidiasis, and bacterial vaginosis (Barbone et al). 1990;163:510-4
Formation, metabolism, and physiologic importance of catecholestrogens (Ball and Knuppen). 1990;163:2163-70 (Symposium)
Gastrointestinal disease and oral contraception (Hanker). 1990;163:2204-7 (Symposium)
Gastrointestinal metabolism of contraceptive steroids (Back et al). 1990;163:2138-45 (Symposium)
Influence of oral contraceptives on drug therapy (Teichmann). 1990;163:2208-13 (Symposium)

Inhibition of oral contraceptive steroid-metabolizing enzymes by steroids and drugs (Guengerich). 1990;163: 2159-63 (Symposium)
Inhibition of ovulation by low-dose monophasic contraceptive containing gestodene (Thomas and Vankrieken). 1990;163:1404-9 (Supplement)
Interactions with oral contraceptives (Fotherby). 1990;163:2153-9 (Symposium)
Oral contraception in disease states (Breckwoldt et al). 1990;163:2213-6 (Symposium)
Oral contraceptives, lipoproteins, and atherosclerosis (Adams et al). 1990;163:1388-92 (Supplement)
Oral contraceptives and breast cancer (Schlesselman). 1990;163:1379-87 (Supplement)
Oral contraceptives and myocardial infarction (Thorneycroft). 1990;163:1393-7 (Supplement)
Pharmacokinetics and pharmacodynamics of oral contraceptive steroids: factors influencing steroid metabolism (Jung-Hoffmann and Kuhl). 1990;163:2183-97 (Symposium)
Pharmacokinetics of ethinyl estradiol and mestranol (Goldzieher and Brody). 1990;163:2114-9 (Symposium)
Pharmacokinetics of gestagens: some problems (Fotherby). 1990;163:323-8 (Supplement)
Pharmacokinetics of gestodene and ethinyl estradiol after oral administration of a monophasic contraceptive (Täuber et al). 1990;163:1414-20 (Supplement)
Pharmacokinetics of oral contraceptive steroids and drug interaction: conclusion (Kuhl). 1990;163:2216-8 (Symposium)
Pharmacokinetics of oral contraceptive steroids and drug interaction: introduction (Kuhl). 1990;163:2113 (Symposium)
Pharmacokinetics of the contraceptive steroids levonorgestrel and gestodene after single and multiple oral administration to women (Kuhnz). 1990;163:2120-7 (Symposium)
Pharmacologic and pharmacokinetic characteristics of norgestimate and its metabolites (McGuire et al). 1990;163:2127-31 (Symposium)
Prodrugs: Advantage or disadvantage? (Hammerstein). 1990;163:2198-203 (Symposium)
Protein binding of active ingredients and comparison of serum ethinyl estradiol sex hormone–binding globulin, corticosteroid-binding globulin, and cortisol levels in women using a combination of gestodene/ethinyl estradiol (Femovan) or a combination of desogestrel/ethinyl estradiol (Marvelon) and single-dose ethinyl estradiol bioequivalence from both oral contraceptives (Hümpel et al). 1990;163:329-33 (Supplement)
Selected aspects of the pharmacokinetics and metabolism of ethinyl estrogens and their clinical implications (Goldzieher). 1990;163:318-22 (Supplement)
Serum pharmacokinetics of orally administered desogestrel and binding of contraceptive progestogens to sex hormone–binding globulin (Bergink et al). 1990;163:2132-7 (Symposium)

Contraceptives, oral, adverse effects

Cardiovascular death among women under 40 years of age using low-estrogen oral contraceptives and intrauterine devices in Finland from 1975 to 1984 (Hirvonen and Idänpään-Heikkilä). 1990;163:281-4 (Supplement)
Clinical aspects of the relationship between oral contraceptives, abnormalities in carbohydrate metabolism, and the development of cardiovascular disease (Gaspard and Lefebvre). 1990;163:334-43 (Supplement)
Clinical aspects of the relationship between oral contraceptives and abnormalities of the hemostatic system: relation to the development of cardiovascular disease (Kelleher). 1990;163:392-5 (Supplement)
The clinical relevance of oral contraceptive pill–induced plasma lipid changes: facts and fiction (Hoppe). 1990;163:388-91 (Supplement)
Comparative studies of 30 μg ethinyl estradiol combined with gestodene and desogestrel on blood coagulation, fibrinolysis, and platelets (Daly and Bonnar). 1990;163:430-7 (Supplement)
Effects of ethinyl estradiol combined with desogestrel and cyproterone acetate on glucose tolerance and insulin response to an oral glucose load: a one-year randomized, prospective, comparative trial (Jandrain et al). 1990;163:378-81 (Supplement)
Effects of long-term gestodene-containing oral contraceptive administration on hemostasis (Abbate et al). 1990;163:424-9 (Supplement)
Effects of newer oral contraceptives on the inhibition of coagulation and fibrinolysis in relation to dosage and type of steroid (Jespersen et al). 1990;163:396-403 (Supplement)
Effects of oral contraceptives on carbohydrate and lipid metabolisms in a healthy population: the Telecom Study (Simon et al). 1990;163:382-7 (Supplement)
Effects of three combined oral contraceptive preparations containing desogestrel plus ethinyl estradiol on lipid metabolism in comparison with two levonorgestrel preparations (Kloosterboer and Rekers). 1990;163:370-3 (Supplement)
Enhanced generation and resolution of fibrin in women above the age of 30 years using oral contraceptives low in estrogen (Gram et al). 1990;163:438-42 (Supplement)
An epidemiologic survey of cardiovascular disease in women taking oral contraceptives (Thorogood and Vessey). 1990;163:274-81 (Supplement)
Estrogenic effect of gestodene- or desogestrel-containing oral contraceptives on lipoprotein metabolism (Gevers Leuven et al). 1990;163:358-62 (Supplement)
Hemostasis profile in women taking low-dose oral contraceptives (David et al). 1990;163:420-3 (Supplement)
Impairment of glucose tolerance: mechanism of action and impact on the cardiovascular system (Beck-Nielsen et al). 1990;163:292-5 (Supplement)
Influence of oral contraceptives on coagulation tests in native blood and plasma (Kunz et al). 1990;163:417-20 (Supplement)
Low-dose oral contraceptives and carbohydrate metabolism (Godsland et al). 1990;163:348-53 (Supplement)
Mechanism of action of oral contraceptives on carbohydrate metabolism at the cellular level (Skouby et al). 1990;163:343-8 (Supplement)
Metabolic changes during the normal menstrual cycle: a longitudinal study (Lebech et al). 1990;163:414-6 (Supplement)
Metabolic changes during treatment with two different progestogens (Refn et al). 1990;163:374-7 (Supplement)
Oral contraceptives in risk groups: Exclusion or monitoring? (Guillebaud). 1990;163:443-6 (Supplement)
Past use of oral contraceptives and cardiovascular disease: a meta-analysis in the context of the Nurses' Health Study (Stampfer et al). 1990;163:285-91 (Supplement)
Role of plasma lipoproteins in the pathogenesis of atherosclerotic disease, with special reference to sex hormone effects (Tikkanen). 1990;163:296-304 (Supplement)

Contraceptives, oral, adverse effects—cont'd
Some aspects of the relationship between oral contraceptives, lipid abnormalities, and cardiovascular disease (Samsioe and Mattsson). 1990;163:354-8 (Supplement)
Studies on the mechanism of action of oral contraceptives with regard to fibrinolytic variables (Kooistra et al). 1990;163:404-13 (Supplement)
Time-dependent alterations in lipid metabolism during treatment with low-dose oral contraceptives (Kuhl et al). 1990;163:363-9 (Supplement)
Why do we need pharmacokinetic studies? (Hvidberg). 1990;163:316-8 (Supplement)
Cordocentesis; *see* **Fetal blood**
Coronary disease
An epidemiologic survey of cardiovascular disease in women taking oral contraceptives (Thorogood and Vessey). 1990;163:274-81 (Supplement)
Evidence of heterogeneous mechanisms in lipoprotein lipid alterations in hyperandrogenic women (Wild et al). 1990;163:1998-2005
Impairment of glucose tolerance: mechanism of action and impact on the cardiovascular system (Beck-Nielsen et al). 1990;163:292-5 (Supplement)
Low-dose oral contraceptives and carbohydrate metabolism (Godsland et al). 1990;163:348-53 (Supplement)
Oral contraception in disease states (Breckwoldt et al). 1990;163:2213-6 (Symposium)
Prevalence and determinants of estrogen replacement therapy in elderly women (Cauley et al). 1990;163:1438-44
Coronary vessels, physiopathology
Postpartum coronary artery dissection followed by heart transplantation (Curiel et al). 1990;163:538-9
Corpus luteum
Corpus luteum function in early pregnancies is primarily determined by the rate of change of human chorionic gonadotropin levels (Kratzer and Taylor). 1990;163:1497-502
Oxytocin and vasopressin binding sites in human and bovine ovaries (Fuchs et al). 1990;163:1961-7

Cysts
Endometrioma of the liver (Rovati et al). 1990;163:1490-2
Management of selected cystic adnexal masses in postmenopausal women by operative laparoscopy: a pilot study (Parker and Berek). 1990;163:1574-7
Cytochrome P-450
Inhibition of oral contraceptive steroid-metabolizing enzymes by steroids and drugs (Guengerich). 1990;163:2159-63 (Symposium)
Cytogenetics
Direct analysis of uncultured cytotrophoblastic cells from second- and third-trimester placentas: an accurate and rapid method for detection of fetal chromosome abnormalities (Shulman et al). 1990;163:1606-9
Cytomegalic inclusion disease, diagnosis
Prenatal diagnosis of congenital cytomegalovirus infection by virus isolation from amniotic fluid (Weiner and Grose). 1990;163:1253-5
Cytomegaloviruses
Prenatal diagnosis of congenital cytomegalovirus infection: two decades later (Grose and Weiner). 1990;163:447-50 (Clin. opinion)
Prenatal diagnosis of fetal intracranial calcifications (Koga et al). 1990;163:1543-5
Cytotoxicity, immunologic
Autologous antibodies eluted from membrane fragments in human ovarian epithelial neoplastic effusions. III. Cytotoxic potential in vitro and characterization of antigen(s) (Kutteh et al). 1990;163:1301-6
Cytotoxicity tests, immunologic
A comparison of sperm antibody assays (Daru and Mathur). 1990;163:1622-9

Cytotrophoblastic cell analysis; *see* **Cytogenetics**

D

Danazol
Effects of danazol, gonadotropin-releasing hormone agonist, and a combination of danazol and gonadotropin-releasing hormone agonist on experimental endometriosis (Sakata et al). 1990;163:1679-84
Death, maternal; *see* **Maternal mortality**
Deceleration
The effect of amnioinfusion on uterine pressure and activity: a preliminary report (Posner et al). 1990;163:813-8
Effect of uterine contractility and maternal hypotension on prolonged decelerations after bupivacaine epidural anesthesia (Steiger and Nageotte). 1990;163:808-12
Decidua
Immunocytochemical distribution and localization of 15-hydroxyprostaglandin dehydrogenase in human fetal membranes, decidua, and placenta (Cheung et al). 1990;163:1445-9
Lymphokine production during term human pregnancy: differences between peripheral leukocytes and decidual cells (Dudley et al). 1990;163:1890-3
Dehydroepiandrosterone
Role of hormones in cervical ripening (Sert). 1990;163:705-7 (Letter)
Delivery
A comparison of the effect of epidural, general, and no anesthesia on funic acid-base values by stage of labor and type of delivery (Shyken et al). 1990;163:802-7
The effect of mode of delivery on the perinatal outcome in fetuses with abdominal wall defects (Moretti et al). 1990;163:833-8
Fetal gastroschisis and omphalocele: Is cesarean section the best mode of delivery? (Lewis et al). 1990;163:773-5
Is indicated or spontaneous preterm delivery more advantageous for the fetus? (Owen et al). 1990;163:868-72
Preterm delivery: a risk factor for retained placenta (Romero et al). 1990;163:823-5
Vaginal birth after abdominal delivery (Thorp and Bowes). 1990;163:1101-2 (Letter)
Vaginal birth after cesarean section: an appraisal of the reappraisal (Flamm) (Letter); (Yetman) (Reply). 1990;163:691-2
Vaginal breech delivery: a five-year prospective evaluation of a protocol using computed tomographic pelvimetry (Christian et al). 1990;163:848-55
Deoxyribonucleic acid fingerprints; *see* **Nucleotide mapping**
Descending aorta; *see* **Aorta, thoracic**
Desogestrel
Binding of oral contraceptive progestogens to serum proteins and cytoplasmic receptor (Juchem and Pollow). 1990;163:2171-83 (Symposium)
Gastrointestinal metabolism of contraceptive steroids (Back et al). 1990;163:2138-45 (Symposium)
Pharmacokinetics and pharmacodynamics of oral contraceptive steroids: factors influencing steroid metabolism (Jung-Hoffmann and Kuhl). 1990;163:2183-97 (Symposium)
Serum pharmacokinetics of orally administered desogestrel and binding of contraceptive progestogens to sex hormone–binding globulin (Bergink et al). 1990;163:2132-7 (Symposium)
Desogestrel/ethinyl estradiol
Comparative studies of 30 μg ethinyl estradiol combined with gestodene and desogestrel on blood coagulation, fibrinolysis, and platelets (Daly and Bonnar). 1990;163:430-7 (Supplement)
Effects of ethinyl estradiol combined with desogestrel and cyproterone acetate on glucose tolerance and insulin response to an oral glucose load: a one-year randomized, prospective, comparative trial (Jandrain et al). 1990;163:378-81 (Supplement)
Effects of newer oral contraceptives on the inhibition of coagulation and fibrinolysis in relation to dosage and type of steroid (Jespersen et al). 1990;163:396-403 (Supplement)
Effects of three combined oral contraceptive preparations containing desogestrel plus ethinyl estradiol on lipid metabolism in comparison with two levonorgestrel preparations (Kloosterboer and Rekers). 1990;163:370-3 (Supplement)
Estrogenic effect of gestodene- or desogestrel-containing oral contraceptives on lipoprotein metabolism (Gevers Leuven et al). 1990;163:358-62 (Supplement)
Protein binding of active ingredients and comparison of serum ethinyl estradiol sex hormone–binding globulin, corticosteroid-binding globulin, and cortisol levels in women using a combination of gestodene/ethinyl estradiol (Femovan) or a combination of desogestrel/ethinyl estradiol (Marvelon) and single-dose ethinyl estradiol bioequivalence from both oral contraceptives (Hümpel et al). 1990;163:329-33 (Supplement)
Time-dependent alterations in lipid metabolism during treatment with low-dose oral contraceptives (Kuhl et al). 1990;163:363-9 (Supplement)
Dextrans
Safety of 32% dextran 70 for hysteroscopy (Ljungström) (Letter); (Jedeikin and Olsfanger) (Reply). 1990;163:2029-30
Diabetes, pregnancy and; *see* **Pregnancy in diabetes**
Diabetes insipidus
Indomethacin treatment for polyhydramnios and subsequent infantile nephrogenic diabetes insipidus (Smith et al). 1990;163:98-9
Diabetes mellitus
Infants of diabetic mothers with accelerated fetal growth by ultrasonography: Are they all alike? (Keller et al). 1990;163:893-7
Oral contraception in disease states (Breckwoldt et al). 1990;163:2213-6 (Symposium)
Prevalence and etiology of respiratory distress in infants of diabetic mothers: predictive value of fetal lung maturation tests (Kjos et al). 1990;163:898-903
Diabetes mellitus, insulin-dependent
Diabetic ketoacidosis and insulin resistance with subcutaneous terbutaline infusion: a case report (Tibaldi et al). 1990;163:509-10
Diabetes mellitus, non-insulin-dependent
Gestational diabetes mellitus: the prevalence of glucose intolerance and diabetes mellitus in the first two months post partum (Kjos et al). 1990;163:93-8
Diabetic ketoacidosis; *see* **Acidosis, diabetic; Ketosis, diabetic**
Diabetic mothers; *see* **Pregnancy in diabetes**
Diagnosis, computer-assisted
Blood pressure measured telemetrically from home throughout pregnancy (Mooney et al). 1990;163:30-6
Ultrasonographic fetal weight estimation by an integrated computer-assisted system: Can each laboratory improve its accuracy? (Thompson et al). 1990;163:986-95
Vaginal breech delivery: a five-year prospective evaluation

Diagnosis, computer-assisted—cont'd
of a protocol using computed tomographic pelvimetry (Christian et al). 1990;163:848-55
Diagnosis, differential
Use of serial human chorionic gonadotropin measurements to differentiate between intrauterine and ectopic pregnancies (Kadar) (Letter); (Lindblom et al) (Reply). 1990;163:259-61
Diagnosis, laboratory
Disorders of the hemostatic system and the risk of the development of thrombotic and cardiovascular diseases: limitations of laboratory diagnosis (Kluft). 1990;163:305-12 (Supplement)
The importance of considering clinical usefulness in the evaluation of medical laboratory tests (Sever). 1990;163:678-9 (Letter)
Laboratory identification of the lupus anticoagulant in normal pregnancy and pregnancy-induced hypertension (Riveros et al) (Letter); (Lockwood) (Reply). 1990;163:704-5
Diazoxide
Suppression of serum insulin level by diazoxide does not alter serum testosterone of sex hormone–binding globulin levels in healthy, nonobese women (Nestler et al). 1990;163:1243-6
Diethylstilbestrol, adverse effects
Colposcopy in diethylstilbestrol-exposed offspring (Gimbel) (Letter); (Helmerhorst) (Reply). 1990;163:703
Digoxin-like immunoreactive factor
Digoxin-like immunoreactive factor and respiratory distress syndrome (Goodlin). 1990;163:1091 (Letter)
Dilapan; *see* **Surgical instruments**
Dinoprost
Conservative treatment of ovarian pregnancy by local prostaglandin $F_{2\alpha}$ injection (Koike et al). 1990;163:696 (Letter)
Critical comments on the treatment of tubal pregnancy with prostaglandins (Dietl and Lippert) (Letter); (Egarter and Husslein) (Reply). 1990;163:707-8
Double-blind comparison of intravaginal prostaglandin E_2 gel and "chip" for preinduction cervical ripening (Smith et al). 1990;163:845-7
Dinoprostone
Effect of intravaginal application of prostaglandin E_2 gel on the mechanical properties of the ovine cervix uteri at term (Owiny and Fitzpatrick). 1990;163:657-60
Evidence of a role for protein kinase C in epidermal growth factor–induced prostaglandin E_2 synthesis in amnion cells (Kniss et al). 1990;163:1883-90
The role of fetal membranes in regulating production, transport, and metabolism of prostaglandin E_2 during labor (McCoshen et al). 1990;163:1632-40
Uterine hyperstimulation after low-dose prostaglandin E_2 therapy: tocolytic treatment in 181 cases (Egarter et al). 1990;163:794-6
Disease models, animal
Ovarian granulosa cell tumorigenesis in SWR-derived F1 hybrid mice: preneoplastic follicular abnormality and malignant disease progression (Tennent et al). 1990;163:625-34
Disseminated intravascular coagulation
Explanation of mechanism of Hyskon solution reaction needed (Loffer). 1990;163:2029 (Letter)
DNA, viral
Carbon dioxide laser energy disperses human papillomavirus deoxyribonucleic acid onto treatment fields (Ferenczy et al). 1990;163:1271-4
DNA fingerprinting; *see* **Nucleotide mapping**
DNA probes
Differential diagnosis between complete mole and hydropic abortus by deoxyribonucleic acid fingerprints (Nobunaga et al). 1990;163:634-8
DNA probes, HPV
The use of in situ hybridization to show human papillomavirus deoxyribonucleic acid in metastatic cancer cells within lymph nodes (Lewandowski et al). 1990;163:1333-7
Donor oocytes; *see* **Oocytes**
Donors; *see* **Tissue donors**
Dopamine
Hypothalamic amenorrhea: clinical perspectives, pathophysiology, and management (Liu). 1990;163:1732-6 (Supplement)
Doppler echocardiography; *see* **Echocardiography, Doppler**
Doppler velocimetry; *see* **Flowmeters**
Down's syndrome
Maternal serum Down syndrome screening: free β-protein is a more effective marker than human chorionic gonadotropin (Macri et al). 1990;163:1248-53
Maternal serum unconjugated estriol levels are lower in the presence of fetal Down syndrome (Haddow et al) (Letter); (Macri et al) (Reply). 1990;163:1372-4
Potential prenatal predictions of Down syndrome: a statistical analysis (O'Brien et al). 1990;163:1796-8
Screening for trisomy 21 with ultrasonographic determination of biparietal diameter/femur length ratio (Marquette et al). 1990;163:1604-5
Ultrasonographic detection of the second-trimester fetus with trisomy 18 and trisomy 21 (Ginsberg et al). 1990;163:1186-90
Drug abuse; *see* **Substance abuse**
Drug interactions
Binding of oral contraceptive progestogens to serum proteins and cytoplasmic receptor (Juchem and Pollow). 1990;163:2171-83 (Symposium)
Factors affecting the enterohepatic circulation of oral contraceptive steroids (Orme and Back). 1990;163:2146-52 (Symposium)
Formation, metabolism, and physiologic importance of catecholestrogens (Ball and Knuppen). 1990;163:2163-70 (Symposium)
Gastrointestinal disease and oral contraception (Hanker). 1990;163:2204-7 (Symposium)
Gastrointestinal metabolism of contraceptive steroids (Back et al). 1990;163:2138-45 (Symposium)
Influence of oral contraceptives on drug therapy (Teichmann). 1990;163:2208-13 (Symposium)
Inhibition of oral contraceptive steroid-metabolizing enzymes by steroids and drugs (Guengerich). 1990;163:2159-63 (Symposium)
Interactions with oral contraceptives (Fotherby). 1990;163:2153-9 (Symposium)
Oral contraception in disease states (Breckwoldt et al). 1990;163:2213-6 (Symposium)
Pharmacokinetics and pharmacodynamics of oral contraceptive steroids: factors influencing steroid metabolism (Jung-Hoffmann and Kuhl). 1990;163:2183-97 (Symposium)
Pharmacokinetics of ethinyl estradiol and mestranol (Goldzieher and Brody). 1990;163:2114-9 (Symposium)
Pharmacokinetics of oral contraceptive steroids and drug

interaction: conclusion (Kuhl). 1990;163:2216-8 (Symposium)
Pharmacokinetics of oral contraceptive steroids and drug interaction: introduction (Kuhl). 1990;163:2113 (Symposium)
Pharmacokinetics of the contraceptive steroids levonorgestrel and gestodene after single and multiple oral administration to women (Kuhnz). 1990;163:2120-7 (Symposium)
Pharmacologic and pharmacokinetic characteristics of norgestimate and its metabolites (McGuire et al). 1990;163:2127-31 (Symposium)
Prodrugs: Advantage or disadvantage? (Hammerstein). 1990;163:2198-203 (Symposium)
Serum pharmacokinetics of orally administered desogestrel and binding of contraceptive progestogens to sex hormone–binding globulin (Bergink et al). 1990;163:2132-7 (Symposium)

Drug resistance
Expression of P-glycoprotein in epithelial ovarian cancer: evaluation as a marker of multidrug resistance (Rubin et al). 1990;163:69-73

Drug therapy
The prognostic significance of CA 125 half-life in patients with ovarian cancer who have received primary chemotherapy after surgical cytoreduction (Hunter et al). 1990;163:1164-7
Successful conservative management of primary nonmetastatic cervical choriocarcinoma (Ben-Chetrit et al). 1990;163:1161-3

Drug therapy, combination
Combination therapy has potential complications (Frohlich) (Letter); (Snyder and Cardwell) (Reply). 1990;163:244

Ductus arteriosus
Ductus arteriosus flow velocity modulation by fetal breathing movements as a measure of fetal lung development (van Eyck et al). 1990;163:558-66

Dyspareunia
Laparoscopic ventrosuspensions (Yoong). 1990;163:1151-3

Dystocia
Can shoulder dystocia be predicted? (Gimbel) (Letter); (O'Leary) (Reply). 1990;163:680
Can shoulder dystocia be prevented? (Nagey) (Letter); (O'Leary) (Reply). 1990;163:1095-6
Epidural analgesia and cesarean section for dystocia (Chestnut) (Letter); (Thorp and Parisi) (Reply). 1990;163:247-9
Labor epidural analgesia and dystocia-related cesarean section (Downing and Knape). 1990;163:1096-7 (Letter)

E

Eating disorders
Infertility and eating disorders (Stewart et al). 1990;163:1196-9

Echo-planar imaging; *see* **Magnetic resonance imaging**

Echocardiography
Prognostic indicators of the resolution of nonimmune hydrops fetalis and survival of the fetus (Carlson et al). 1990;163:1785-7

Echocardiography, Doppler
Assessment of cerebral hemodynamics in pregnant women by internal carotid artery pulsed Doppler velocimetry (Ikeda and Mori). 1990;163:494-8
Blood flow velocity and pulsatile diameter changes in the fetal descending aorta: a longitudinal study (Stale et al). 1990;163:26-9
Ductus arteriosus flow velocity modulation by fetal breathing movements as a measure of fetal lung development (van Eyck et al). 1990;163:558-66
Prenatal diagnosis of a chest wall mass with ultrasonography and Doppler velocimetry: a case report (Smith et al). 1990;163:567-9
Relationship between the ovine fetal umbilical artery blood flow waveform and umbilical vascular resistance (Irion and Clark). 1990;163:222-9

Eclampsia
Eclampsia. VI. Maternal-perinatal outcome in 254 consecutive cases (Sibai). 1990;163:1049-55
Epidemiology of preeclampsia and eclampsia in the United States, 1979-1986 (Saftlas et al). 1990;163:460-5
Magnesium sulfate is not an ideal anticonvulsant (Goodlin) (Letter); (Sibai) (Reply). 1990;163:1714-5
National High Blood Pressure Education Program Working Group report on high blood pressure in pregnancy. 1990;163:1691-712 (Supplement)
Phenytoin and magnesium sulfate in eclampsia (Dommisse) (Letter); (Ryan) (Reply). 1990;163:1089-91

Ectopic pregnancy; *see* **Pregnancy, ectopic**

Edema
False-negative syphilis screening: the prozone phenomenon, nonimmune hydrops, and diagnosis of syphilis during pregnancy (Berkowitz et al). 1990;163:975-7

Editorial
Editorial. 1990;163:1109-10

Education, medical
Does obstetric ethics have any role in the obstetrician's response to the abortion controversy? (Chervenak and McCullough). 1990;163:1425-9 (Clin. opinion)

Egg transport; *see* **Ovum transport**

Eicosanoids
Low-dose aspirin. II. Relationship of angiotensin II pressor responses, circulating eicosanoids, and pregnancy outcome (Brown et al). 1990;163:1853-61

Electric conductivity
Ovulation prediction from cyclic changes in salivary electrical conductivity (Loewit et al). 1990;163:708-10 (Letter)

Electrocardiography
Effects of ritodrine tocolysis on cardiac isozymes and electrocardiography (Hendricks and Katz) (Letter); (Hadi and Albazzaz) (Reply). 1990;163:699-701

ELISA; *see* **Enzyme-linked immunosorbent assay**

Embolism, air
Hyperbaric oxygen therapy for air embolism complicating operative hysteroscopy (Tur-Kaspa) (Letter); (Baggish) (Reply). 1990;163:680-1
Sapphire probes in obstetric laser surgery (Corson) (Letter); (Baggish and Daniell) (Reply). 1990;163:246-7

Embolism, amniotic fluid
Successful treatment of postpartum shock caused by amniotic fluid embolism with cardiopulmonary bypass and pulmonary artery thromboembolectomy (Esposito et al). 1990;163:572-4

Embryo
Distribution of CA 125 in embryonic tissues and adult derivatives of the fetal periderm (Hardardottir et al). 1990;163:1925-31
Embryo migration responsible for ectopic pregnancies (Rizk). 1990;163:1369 (Letter)
Embryopathic effects of short-term exposure to hypoglycemia in mouse embryos in vitro (Smoak and Sadler). 1990;163:619-24

Embryo development; *see* **Fetal development**
Embryo implantation; *see* **Ovum implantation**
Endocrine diseases
Multiple endocrine adenomatosis type I in pregnancy (Smythe et al). 1990;163:1037-9
Endometrial carcinoma; *see* **Carcinoma**
Endometrioma of liver; *see* **Endometriosis**
Endometriosis
Collagen metabolism in gynecologic patients: changes in the concentration of the aminoterminal propeptide of type III procollagen in serum (Puistola et al). 1990;163:1276-81
Endometrioma of the liver (Rovati et al). 1990;163:1490-2
Immunohistochemical localization of prostaglandin H synthase in the female reproductive tract and endometriosis (Van Voorhis et al). 1990;163:57-62
Studies of the spontaneous motility and the effect of histamine on isolated myometrial strips of the nonpregnant human uterus: the influence of various uterine abnormalities (Martinez-Mir et al). 1990;163:189-95
The use of serial CA 125 concentrations to monitor endometriosis in infertile women (Pittaway). 1990;163:1032-7
Endometriosis, animal
Effects of danazol, gonadotropin-releasing hormone agonist, and a combination of danazol and gonadotropin-releasing hormone agonist on experimental endometriosis (Sakata et al). 1990;163:1679-84
Endometrium
Comparison of norethindrone and medroxyprogesterone acetate with natural progesterone and estradiol in stimulating prolactin production from cultured endometrial stromal cells (Levin et al). 1990;163:1932-8
Endometrial assessment by vaginal ultrasonography before endometrial sampling in patients with postmenopausal bleeding (Goldstein et al). 1990;163:119-23
Epithelial cells from normal human endometrium express a tumor-associated glycoprotein (TAG-72) epitope in vitro (Osteen et al). 1990;163:479-84
Experience with the EndoPap device for the cytologic detection of uterine cancer and its precursors: a comparison of the EndoPap with fractional curettage or hysterectomy (LaPolla et al). 1990;163:1055-60
Immunohistochemical localization of prostaglandin H synthase in the female reproductive tract and endometriosis (Van Voorhis et al). 1990;163:57-62
Interleukin-1β, human leukocyte antigen DR1, and transforming growth factor-β expression in endometrium, placenta, and placental membranes (Kauma et al). 1990;163:1430-7
Endopap device; *see* **Uterus**
Endorphins
Hypothalamic amenorrhea: clinical perspectives, pathophysiology, and management (Liu). 1990;163:1732-6 (Supplement)
Neuromodulatory regulation of gonadotropin-releasing hormone pulsatile discharge in women (Jaffe et al). 1990;163:1727-31 (Supplement)
Endothelial cells; *see* **Endothelium, vascular**
Endothelium, vascular
Studies on the mechanism of action of oral contraceptives with regard to fibrinolytic variables (Kooistra et al). 1990;163:404-13 (Supplement)
Endothelium, vascular, animal
Role of the endothelium in adrenergic responses of mesenteric artery rings of pregnant rats (Parent et al). 1990;163:229-34
Enterohepatic circulation
Factors affecting the enterohepatic circulation of oral contraceptive steroids (Orme and Back). 1990;163:2146-52 (Symposium)
Enzyme-linked immunosorbent assay
Comparison of a rapid enzyme-linked immunosorbent assay test and the Gram stain for detection of group B streptococcus in high-risk antepartum patients (Towers et al). 1990;163:965-7
Epidermal growth factor-urogastrone
Evidence of a role for protein kinase C in epidermal growth factor–induced prostaglandin E_2 synthesis in amnion cells (Kniss et al). 1990;163:1883-90
Epidural analgesia; *see* **Analgesia, epidural**
Epithelium
Epithelial cells from normal human endometrium express a tumor-associated glycoprotein (TAG-72) epitope in vitro (Osteen et al). 1990;163:479-84
Epitopes; *see* **Antigenic determinants**
Erythroblastosis, fetal
Postinjection kinetics of antepartum Rh immune globulin (Witter et al). 1990;163:784-6
Erythrocytes, immunology
Acute fetal hemodynamic alterations after intrauterine transfusion for treatment of severe red cell alloimmunization (Moise et al). 1990;163:776-84
Erythromycin
Cervicovaginal microflora and pregnancy outcome: results of a double-blind, placebo-controlled trial of erythromycin treatment (McGregor et al). 1990;163:1580-91
Esterases
In vitro inhibition of esterase activity in amniotic fluid: comparison with bacterial cultures (Hoskins et al). 1990;163:1944-7
Estradiol
Comparison of norethindrone and medroxyprogesterone acetate with natural progesterone and estradiol in stimulating prolactin production from cultured endometrial stromal cells (Levin et al). 1990;163:1932-8
Isolation and characterization of the gene from a human genome encoding 17β-estradiol dehydrogenase: a comparison of Jar and BeWo choriocarcinoma cell lines (Long et al). 1990;163:1976-81
The relationship between plasma estradiol and the increase in bone density in postmenopausal women after treatment with subcutaneous hormone implants (Studd et al). 1990;163:1474-9
Short-term effects of smoking on the pharmacokinetic profiles of micronized estradiol in postmenopausal women (Cassidenti et al). 1990;163:1953-60
Estriol
Maternal serum unconjugated estriol levels are lower in the presence of fetal Down syndrome (Haddow et al) (Letter); (Macri et al) (Reply). 1990;163:1372-4
Estrogen antagonists
The clinical relevance of oral contraceptive pill–induced plasma lipid changes: facts and fiction (Hoppe). 1990;163:388-91 (Supplement)
Estrogen receptors, animal; *see* **Receptors, estrogen, animal**
Estrogen replacement therapy
Effects on bone of surgical menopause and estrogen therapy with or without progesterone replacement in cynomolgus monkeys (Jayo et al). 1990;163:614-8

Prevalence and determinants of estrogen replacement therapy in elderly women (Cauley et al). 1990;163: 1438-44
The relationship between plasma estradiol and the increase in bone density in postmenopausal women after treatment with subcutaneous hormone implants (Studd et al). 1990;163:1474-9
Short-term effects of smoking on the pharmacokinetic profiles of micronized estradiol in postmenopausal women (Cassidenti et al). 1990;163:1953-60

Estrogens
Comparative studies of 30 μg ethinyl estradiol combined with gestodene and desogestrel on blood coagulation, fibrinolysis, and platelets (Daly and Bonnar). 1990;163:430-7 (Supplement)
Effects of ethinyl estradiol combined with desogestrel and cyproterone acetate on glucose tolerance and insulin response to an oral glucose load: a one-year randomized, prospective, comparative trial (Jandrain et al). 1990;163:378-81 (Supplement)
Effects of newer oral contraceptives on the inhibition of coagulation and fibrinolysis in relation to dosage and type of steroid (Jespersen et al). 1990;163:396-403 (Supplement)
Effects of oral contraceptives on carbohydrate and lipid metabolisms in a healthy population: the Telecom Study (Simon et al). 1990;163:382-7 (Supplement)
Efficacy and safety considerations in women with uterine leiomyomas treated with gonadotropin-releasing hormone agonists: the estrogen threshold hypothesis (Friedman et al). 1990;163:1114-9 (Clin. opinion)
Isolation and characterization of the gene from a human genome encoding 17β-estradiol dehydrogenase: a comparison of Jar and BeWo choriocarcinoma cell lines (Long et al). 1990;163:1976-81
Metabolic changes during treatment with two different progestogens (Refn et al). 1990;163:374-7 (Supplement)
Prodrugs: Advantage or disadvantage? (Hammerstein). 1990;163:2198-203 (Symposium)
Protein binding of active ingredients and comparison of serum ethinyl estradiol sex hormone–binding globulin, corticosteroid-binding globulin, and cortisol levels in women using a combination of gestodene/ethinyl estradiol (Femovan) or a combination of desogestrel/ethinyl estradiol (Marvelon) and single-dose ethinyl estradiol bioequivalence from both oral contraceptives (Hümpel et al). 1990;163:329-33 (Supplement)
Selected aspects of the pharmacokinetics and metabolism of ethinyl estrogens and their clinical implications (Goldzieher). 1990;163:318-22 (Supplement)
Time-dependent alterations in lipid metabolism during treatment with low-dose oral contraceptives (Kuhl et al). 1990;163:363-9 (Supplement)

Ethics
Anencephalics as organ donors (Van Assche). 1990;163:599-600
Does obstetric ethics have any role in the obstetrician's response to the abortion controversy? (Chervenak and McCullough). 1990;163:1425-9 (Clin. opinion)
Drug prophylaxis for human immunodeficiency virus–infected pregnant women: ethical considerations (Minkoff and Moreno). 1990;163:1111-4 (Clin. opinion)
Ethics and routine ultrasonography in pregnancy (Ewigman et al) (Letter); (Chervenak et al) (Reply). 1990;163:256-8
Ethics of new reproductive technologies (Blaskiewicz) (Letter); (Macnaughton) (Reply). 1990;163:1376

Ethinyl estradiol
Clinical acceptability of monophasic gestodene (Düsterberg and Brill). 1990;163:1398-403 (Supplement)
Comparative studies of 30 μg ethinyl estradiol combined with gestodene and desogestrel on blood coagulation, fibrinolysis, and platelets (Daly and Bonnar). 1990;163:430-7 (Supplement)
Effects of ethinyl estradiol combined with desogestrel and cyproterone acetate on glucose tolerance and insulin response to an oral glucose load: a one-year randomized, prospective, comparative trial (Jandrain et al). 1990;163:378-81 (Supplement)
Effects of newer oral contraceptives on the inhibition of coagulation and fibrinolysis in relation to dosage and type of steroid (Jespersen et al). 1990;163:396-403 (Supplement)
Effects of oral contraceptives on lipid metabolism (Gevers Leuven et al). 1990;163:1410-3 (Supplement)
Factors affecting the enterohepatic circulation of oral contraceptive steroids (Orme and Back). 1990;163:2146-52 (Symposium)
Gastrointestinal metabolism of contraceptive steroids (Back et al). 1990;163:2138-45 (Symposium)
Inhibition of oral contraceptive steroid-metabolizing enzymes by steroids and drugs (Guengerich). 1990;163: 2159-63 (Symposium)
Inhibition of ovulation by low-dose monophasic contraceptive containing gestodene (Thomas and Vankrieken). 1990;163:1404-9 (Supplement)
Metabolic changes during treatment with two different progestogens (Refn et al). 1990;163:374-7 (Supplement)
Pharmacokinetics and pharmacodynamics of oral contraceptive steroids: factors influencing steroid metabolism (Jung-Hoffmann and Kuhl). 1990;163:2183-97 (Symposium)
Pharmacokinetics of ethinyl estradiol and mestranol (Goldzieher and Brody). 1990;163:2114-9 (Symposium)
Pharmacokinetics of gestodene and ethinyl estradiol after oral administration of a monophasic contraceptive (Täuber et al). 1990;163:1414-20 (Supplement)
Protein binding of active ingredients and comparison of serum ethinyl estradiol sex hormone–binding globulin, corticosteroid-binding globulin, and cortisol levels in women using a combination of gestodene/ethinyl estradiol (Femovan) or a combination of desogestrel/ethinyl estradiol (Marvelon) and single-dose ethinyl estradiol bioequivalence from both oral contraceptives (Hümpel et al). 1990;163:329-33 (Supplement)
Selected aspects of the pharmacokinetics and metabolism of ethinyl estrogens and their clinical implications (Goldzieher). 1990;163:318-22 (Supplement)
Time-dependent alterations in lipid metabolism during treatment with low-dose oral contraceptives (Kuhl et al). 1990;163:363-9 (Supplement)

Ethinyl estradiol with desogestrel; *see* **Desogestrel/ethinyl estradiol**

Ethinyl estradiol with gestodene; *see* **Gestodene/ethinyl estradiol**

Ethnic groups
Glucose tolerance in pregnancy: ethnic variation and influence of body habitus (Green et al). 1990;163:86-92

Evaluation studies
The importance of considering clinical usefulness in the evaluation of medical laboratory tests (Sever). 1990;163:678-9 (Letter)

Exercise
The course of labor after endurance exercise during pregnancy (Clapp). 1990;163:1799-805
The effect of physical activity during pregnancy on preterm delivery and birth weight (Klebanoff et al). 1990;163:1450-6
Fetal umbilical artery Doppler response to graded maternal aerobic exercise and subsequent maternal mean arterial blood pressure: predictive value for pregnancy-induced hypertension (Hume et al). 1990;163:826-9
Maternal exercise and early pregnancy outcome (Suzuki and Miller). 1990;163:1103 (Letter)
Neonatal morphometrics after endurance exercise during pregnancy (Clapp and Capeless). 1990;163:1805-11
Extrahepatic biliary tree; *see* **Biliary tract**
Eye, physiopathology
Neuroophthalmologic effects of intravenous magnesium sulfate (Digre et al). 1990;163:1848-52
Eye movements
Fetal eye movement assessed with real-time ultrasonography: Are there rapid and slow eye movements? (Horimoto et al). 1990;163:1480-4

F

Factor analysis, statistical
Potential prenatal predictions of Down syndrome: a statistical analysis (O'Brien et al). 1990;163:1796-8
Factor VII
Clinical aspects of the relationship between oral contraceptives and abnormalities of the hemostatic system: relation to the development of cardiovascular disease (Kelleher). 1990;163:392-5 (Supplement)
Effects of long-term gestodene-containing oral contraceptive administration on hemostasis (Abbate et al). 1990;163:424-9 (Supplement)
Fallopian tubes
The complex nature of egg transport through the oviduct (Egarter) (Letter); (Pulkkinen and Jaakkola) (Reply). 1990;163:687-8
Necrotizing fasciitis of the total abdominal wall after sterilization by partial salpingectomy (Cederna et al). 1990;163:138-9
False negative reactions
False-negative syphilis screening: the prozone phenomenon, nonimmune hydrops, and diagnosis of syphilis during pregnancy (Berkowitz et al). 1990;163:975-7
Family planning
Contraception and ectopic pregnancy risk (Franks et al). 1990;163:1120-3
Fasciitis
Necrotizing fasciitis of the total abdominal wall after sterilization by partial salpingectomy (Cederna et al). 1990;163:138-9
Fatty liver
Pregnancy-induced hypertension and acute fatty liver of pregnancy: atypical presentations (Brown et al). 1990;163:1154-6
Recurrent acute fatty liver of pregnancy (Barton et al). 1990;163:534-8
Femovan; *see* **Gestodene/ethinyl estradiol**
Fertilization
5-Fluorouracil exposure during the period of conception: report on two cases (Odom et al). 1990;163:76-7
Lymphocyte proliferative response to fertilization antigen in patients with antisperm antibodies (Naz et al). 1990;163:610-3
Fertilization in vitro
Factors affecting embryo implantation after human in vitro fertilization: a hypothesis (Paulson et al). 1990;163:2020-3
Heterotopic pregnancy associated with assisted reproductive technology (Dimitry et al). 1990;163:244-5 (Letter)
How sperm commence movement and their isolation for in vitro fertilization and sex selection (Shettles). 1990;163:270 (Letter)
Tubal embryo successfully transferred in utero (Shettles). 1990;163:2026-7 (Letter)
Fertilization in vitro, animal
In vitro effect of RU 486 on sperm-egg interaction in mice (Juneja and Dodson). 1990;163:216-21
Platelet activating factor enhances in vitro fertilization of rabbit oocytes (Roudebush et al). 1990;163:1670-3
Fetal acidemia; *see* **Fetal distress**
Fetal acoustic stimulation; *see* **Acoustic stimulation**
Fetal anoxia
The association of intrapartum asphyxia in the mature fetus with newborn behavior (Low et al). 1990;163:1131-5
Definition of fetal asphyxia (Clark) (Letter); (Johnson and Richards) (Reply). 1990;163:1364
Fetal anoxia, animal
Hypoxic acidemia, hyperviscosity, and maternal hypertension do not affect the umbilical arterial velocity waveform in fetal sheep (Morrow et al). 1990;163:1313-20
Role of vasopressin in mediation of fetal cardiovascular responses to acute hypoxia (Piacquadio et al). 1990;163:1294-300
Fetal blood
Continuing controversy in alloimmune thrombocytopenia: fetal hyperimmunoglobulinemia fails to prevent thrombocytopenia (Nicolini et al). 1990;163:1144-6
Cordocentesis and immune thrombocytopenia—continued (Weiner). 1990;163:1371-2 (Letter)
Detection of fetal blood contamination by amniotic fluid obtained during cordocentesis (Lazebnik et al). 1990;163:78-80
Effects of magnesium and isradipine on contractile activation induced by the thromboxane A_2 analog U46619 in human uteroplacental arteries in term pregnancy (Skajaa et al). 1990;163:1323-33
Possible therapeutic applications of cordocentesis (Sherer and Abramowicz). 1990;163:1366-7 (Letter)
Relationship of fetal biophysical profile and blood gas values at cordocentesis in severely growth-retarded fetuses (Ribbert et al). 1990;163:569-71
Fetal blood, animal
Relationship between the ovine fetal umbilical artery blood flow waveform and umbilical vascular resistance (Irion and Clark). 1990;163:222-9
Venous and hepatic vascular responses to indomethacin and prostaglandin E_1 in the fetal lamb (Paulick et al). 1990;163:1357-63
Fetal blood transfusion; *see* **Blood transfusion, intrauterine**
Fetal breathing movement; *see* **Fetal monitoring**
Fetal death
The association of maternal floor infarction of the placenta with adverse perinatal outcome (Andres et al). 1990;163:935-8
The effect of race on the relationship between fetal death

and altered fetal growth (Ferguson and Myers). 1990;163:1222-30
Induction of labor with mifepristone (RU 486) in intrauterine fetal death (Cabrol et al). 1990;163:540-2
Postmortem chorionic villus sampling is a better method for cytogenetic evaluation of early fetal loss than culture of abortus material (Johnson et al). 1990;163:1505-10
Recurrent adverse pregnancy outcome and antiphospholipid antibodies (Reece et al). 1990;163:162-9 (Curr. dev.)
Study results vary in count-to-10 method of fetal movement screening (Elbourne and Grant) (Letter); (Moore and Piacquadio) (Reply). 1990;163:264-5
Survival in a fetus with sacrococcygeal teratoma and hydrops (Nakayama). 1990;163:682 (Letter)

Fetal death, animal
Immunoglobulin G fractions from patients with antiphospholipid antibodies cause fetal death in BALB/c mice: a model for autoimmune fetal loss (Branch et al). 1990;163:210-6

Fetal development
Blood flow velocity and pulsatile diameter changes in the fetal descending aorta: a longitudinal study (Stale et al). 1990;163:26-9
Cocaine effects on fetal behavioral state (Tabor and Soffici) (Letter); (Hume) (Reply). 1990;163:1364-5
The differential neonatal morbidity of the intrauterine growth retardation syndrome (Villar et al). 1990;163:151-7
Distribution of CA 125 in embryonic tissues and adult derivatives of the fetal periderm (Hardardottir et al). 1990;163:1925-31
Ductus arteriosus flow velocity modulation by fetal breathing movements as a measure of fetal lung development (van Eyck et al). 1990;163:558-66
Growth of linear parameters in trisomy 18 fetuses (Droste et al). 1990;163:158-61
Insulin-like growth factor II and nonsuppressible insulin-like activity levels in newborns (Samaan et al). 1990;163:1836-9
Is indicated or spontaneous preterm delivery more advantageous for the fetus? (Owen et al). 1990;163:868-72
Metabolism of cocaine by human placentas: implications for fetal exposure (Roe et al). 1990;163:715-8
Neonatal morphometrics after endurance exercise during pregnancy (Clapp and Capeless). 1990;163:1805-11
Second-trimester ultrasonography: determinants of visualization of fetal anatomic structures (Catanzarite and Quirk). 1990;163:1191-5
Study of internal structure of the human fetus in utero by echo-planar magnetic resonance imaging (Johnson et al). 1990;163:601-7
Ultrasonographic fetal weight estimation by an integrated computer-assisted system: Can each laboratory improve its accuracy? (Thompson et al). 1990;163:986-95

Fetal development, animal
Dose response of thyrotropin-releasing hormone on pulmonary maturation in corticosteroid-treated preterm rabbits (Tabor et al). 1990;163:669-76
Effects of clonidine on breathing movements and electrocortical activity in the fetal lamb (Bamford et al). 1990;163:661-8
Embryopathic effects of short-term exposure to hypoglycemia in mouse embryos in vitro (Smoak and Sadler). 1990;163:619-24
Venous and hepatic vascular responses to indomethacin and prostaglandin E_1 in the fetal lamb (Paulick et al). 1990;163:1357-63

Fetal diseases
Antenatal diagnosis of molybdenum cofactor deficiency (George et al). 1990;163:1203-4
Antenatal spontaneous perforation of the extrahepatic biliary tree (Chilukuri et al). 1990;163:1201-2
Diagnosis and management of prenatally detected myelomeningocele: a preliminary report (Hogge et al). 1990;163:1061-5
Prenatal diagnosis of fetal intracranial calcifications (Koga et al). 1990;163:1543-5
Second-trimester ultrasonography: determinants of visualization of fetal anatomic structures (Catanzarite and Quirk). 1990;163:1191-5
Spontaneous resolution of a nuchal fetal cystic hygroma diagnosed early in the second trimester of pregnancy (Meizner et al) (Letter); (Bronshstein and Blumenfeld) (Reply). 1990;163:267-9
Survival in a fetus with sacrococcygeal teratoma and hydrops (Nakayama). 1990;163:682 (Letter)
Ultrasonographic assessment of intestinal damage in fetuses with gastroschisis: Is it of clinical value? (Lenke et al). 1990;163:995-8

Fetal distress
Cerebral palsy and intrapartum fetal acidemia (Goodlin) (Letter); (Dennis et al) (Reply). 1990;163:266-7
Definition of fetal asphyxia (Clark) (Letter); (Johnson and Richards) (Reply). 1990;163:1364
Fetal heart rate monitoring during cesarean section (Dunn) (Letter); (Petrikovsky et al) (Reply). 1990;163:253

Fetal growth retardation
The association of maternal floor infarction of the placenta with adverse perinatal outcome (Andres et al). 1990;163:935-8
The differential neonatal morbidity of the intrauterine growth retardation syndrome (Villar et al). 1990;163:151-7
The effect of maternal hyperoxia on behavioral activity in growth-retarded human fetuses (Gagnon et al). 1990;163:1894-9
Effect of mitral valve prosthetic surgery on the outcome of a growth-retarded fetus: a case report (Izquierdo et al). 1990;163:584-7
The effect of race on the relationship between fetal death and altered fetal growth (Ferguson and Myers). 1990;163:1222-30
Growth of linear parameters in trisomy 18 fetuses (Droste et al). 1990;163:158-61
Hypoxic acidemia, hyperviscosity, and maternal hypertension do not affect the umbilical arterial velocity waveform in fetal sheep (Morrow et al). 1990;163:1313-20
Is intrauterine transfusion associated with diminished fetal growth? (Utter et al). 1990;163:1781-4
Maternal serum α-fetoprotein levels in pregnancies complicated by diabetes: implications for screening programs (Martin et al). 1990;163:1209-16
Relationship of fetal biophysical profile and blood gas values at cordocentesis in severely growth-retarded fetuses (Ribbert et al). 1990;163:569-71

Fetal heart
Accuracy of apical four-chamber view as screen for congenital heart disease (Stephens). 1990;163:249-50 (Letter)
Acute fetal hemodynamic alterations after intrauterine

Fetal heart—cont'd
transfusion for treatment of severe red cell alloimmunization (Moise et al). 1990;163:776-84
Variation and correlation in human fetal umbilical Doppler velocities with fetal breathing: evidence of the cardiac-placental connection (Indik and Reed). 1990;163:1792-6
Fetal heart rate; *see* **Heart rate, fetal**
Fetal heart rate deceleration; *see* **Deceleration**
Fetal hypoxia; *see* **Fetal anoxia**
Fetal lung hypoplasia; *see* **Fetal organ maturity**
Fetal macrosomia; *see* **Macrosomia**
Fetal membranes
Cases with ruptured membranes that "reseal" (Johnson et al). 1990;163:1024-32
Immunocytochemical distribution and localization of 15-hydroxyprostaglandin dehydrogenase in human fetal membranes, decidua, and placenta (Cheung et al). 1990;163:1445-9
The role of fetal membranes in regulating production, transport, and metabolism of prostaglandin E_2 during labor (McCoshen et al). 1990;163:1632-40
Fetal membranes, premature rupture
Antibiotic therapy in preterm premature rupture of membranes: a randomized, prospective, double-blind trial (Johnston et al). 1990;163:743-7
Cases with ruptured membranes that "reseal" (Johnson et al). 1990;163:1024-32
Cervicovaginal microflora and pregnancy outcome: results of a double-blind, placebo-controlled trial of erythromycin treatment (McGregor et al). 1990;163:1580-91
Gram stain results from amniocentesis in patients with preterm permature rupture of membranes—comparison of maternal and fetal characteristics (Asrat et al). 1990;163:887-9
Normal amniotic pressure in oligohydramnios after preterm rupture of membranes (Johnson and Maxwell) (Letter); (Nicolini et al) (Reply). 1990;163:1103-4
Perinatal survival with expectant management of midtrimester rupture of membranes (Major and Kitzmiller). 1990;163:838-44
Risk factors for preterm premature rupture of fetal membranes: a multicenter case-control study (Harger et al). 1990;163:130-7
Fetal membranes, prolonged rupture
Direct ultrasonographic measurement of fetal lung length in normal pregnancies and pregnancies complicated by prolonged rupture of membranes (Roberts and Mitchell). 1990;163:1560-6
Fetal monitoring
Acute fetal hemodynamic alterations after intrauterine transfusion for treatment of severe red cell alloimmunization (Moise et al). 1990;163:776-84
Cocaine effects on fetal behavioral state (Tabor and Soffici) (Letter); (Hume) (Reply). 1990;163:1364-5
The diagnostic values of concurrent nonstress testing, amniotic fluid measurement, and Doppler velocimetry in screening a general high-risk population (Devoe et al). 1990;163:1040-8
Effect of tocolytic agents on fetal umbilical velocimetry (Wright et al). 1990;163:748-50
Effects of hypertension on pregnancy monitoring and results (Lenox et al). 1990;163:1173-9
Fetal heart rate monitoring during cesarean section (Dunn) (Letter); (Petrikovsky et al) (Reply). 1990;163:253
The intrauterine sound environment of the human fetus during labor (Benzaquen et al). 1990;163:484-90
Relationship of fetal biophysical profile and blood gas values at cordocentesis in severely growth-retarded fetuses (Ribbert et al). 1990;163:569-71
Two-tier approach to biophysical assessment of the fetus (Mills et al). 1990;163:12-7
Fetal monitoring, animal
Effects of clonidine on breathing movements and electrocortical activity in the fetal lamb (Bamford et al). 1990;163:661-8
Fetal movement
Differential sensitivities of fetal muscle groups to *d*-tubocurarine (Szeto and Hinman). 1990;163:202-9
Effect of maternal-fetal movement on concentration of cells obtained at genetic amniocentesis (Carlan et al). 1990;163:490-3
Fetal eye movement assessed with real-time ultrasonography: Are there rapid and slow eye movements? (Horimoto et al). 1990;163:1480-4
Study results vary in count-to-10 method of fetal movement screening (Elbourne and Grant) (Letter); (Moore and Piacquadio) (Reply). 1990;163:264-5
Vibroacoustic stimulation and fetal behavioral state in normal term human pregnancy (Devoe et al). 1990;163:1156-61
Fetal organ maturity
Absence of evidence of pulmonary maturity at amniocentesis in term infants of diabetic mothers (Ojomo and Coustan). 1990;163:954-7
Blood flow velocity and pulsatile diameter changes in the fetal descending aorta: a longitudinal study (Stale et al). 1990;163:26-9
Digoxin-like immunoreactive factor and respiratory distress syndrome (Goodlin). 1990;163:1091 (Letter)
Direct ultrasonographic measurement of fetal lung length in normal pregnancies and pregnancies complicated by prolonged rupture of membranes (Roberts and Mitchell). 1990;163:1560-6
Ductus arteriosus flow velocity modulation by fetal breathing movements as a measure of fetal lung development (van Eyck et al). 1990;163:558-66
Is indicated or spontaneous preterm delivery more advantageous for the fetus? (Owen et al). 1990;163:868-72
Prevalence and etiology of respiratory distress in infants of diabetic mothers: predictive value of fetal lung maturation tests (Kjos et al). 1990;163:898-903
Study of internal structure of the human fetus in utero by echo-planar magnetic resonance imaging (Johnson et al). 1990;163:601-7
Fetal organ maturity, animal
Dose response of thyrotropin-releasing hormone on pulmonary maturation in corticosteroid-treated preterm rabbits (Tabor et al). 1990;163:669-76
Effects of clonidine on breathing movements and electrocortical activity in the fetal lamb (Bamford et al). 1990;163:661-8
A mechanism leading to reduced lung expansion and lung hypoplasia in fetal sheep during oligohydramnios (Harding et al). 1990;163:1904-13
Fetal outcome; *see* **Pregnancy outcome**
Fetal pulmonary hypoplasia; *see* **Fetal organ maturity**
Fetal sex determination; *see* **Sex determination**
Fetal umbilical velocimetry; *see* **Flowmeters**
Fetal viability
Does obstetric ethics have any role in the obstetrician's re-

sponse to the abortion controversy? (Chervenak and McCullough). 1990;163:1425-9 (Clin. opinion)
Prognostic indicators of the resolution of nonimmune hydrops fetalis and survival of the fetus (Carlson et al). 1990;163:1785-7

Fetofetal transfusion
Discrepancies in hemoglobin levels (Giles et al). 1990;163:1713 (Letter)
Twin-to-twin transfusion syndrome (Blickstein) (Letter); (Neilson) (Reply). 1990;163:677-8
Twin transfusion syndrome (Baldwin) (Letter); (Shah and Chaffin) (Reply). 1990;163:1376-7
Twin-twin transfusion syndrome (Urig et al). 1990;163:1522-6

Fetomaternal transfusion
The incidence of significant fetomaternal hemorrhage in patients undergoing cesarean section (Feldman et al). 1990;163:855-8

α-Fetoproteins; *see* **Alpha fetoproteins**

Fibrin
Enhanced generation and resolution of fibrin in women above the age of 30 years using oral contraceptives low in estrogen (Gram et al). 1990;163:438-42 (Supplement)

Fibrin fibrinogen degradation products
Enhanced generation and resolution of fibrin in women above the age of 30 years using oral contraceptives low in estrogen (Gram et al). 1990;163:438-42 (Supplement)

Fibrinogen
Clinical aspects of the relationship between oral contraceptives and abnormalities of the hemostatic system: relation to the development of cardiovascular disease (Kelleher). 1990;163:392-5 (Supplement)

Fibrinolysis
Comparative studies of 30 μg ethinyl estradiol combined with gestodene and desogestrel on blood coagulation, fibrinolysis, and platelets (Daly and Bonnar). 1990;163:430-7 (Supplement)
Disorders of the hemostatic system and the risk of the development of thrombotic and cardiovascular diseases: limitations of laboratory diagnosis (Kluft). 1990;163:305-12 (Supplement)
Effects of long-term gestodene-containing oral contraceptive administration on hemostasis (Abbate et al). 1990;163:424-9 (Supplement)
Effects of newer oral contraceptives on the inhibition of coagulation and fibrinolysis in relation to dosage and type of steroid (Jespersen et al). 1990;163:396-403 (Supplement)
Hemostasis profile in women taking low-dose oral contraceptives (David et al). 1990;163:420-3 (Supplement)
Studies on the mechanism of action of oral contraceptives with regard to fibrinolytic variables (Kooistra et al). 1990;163:404-13 (Supplement)

Fibrinopeptide A
Effects of long-term gestodene-containing oral contraceptive administration on hemostasis (Abbate et al). 1990;163:424-9 (Supplement)

Fibroids, uterine; *see* **Uterine neoplasms**

Fingerprinting, DNA; *see* **Nucleotide mapping**

Fingerprints, nucleotide; *see* **Nucleotide mapping**

Fistula, vesicovaginal; *see* **Vesicovaginal fistula**

Flow cytometry
Flow cytometric quantitation of tumor-associated antigens in solid tumors (van Dam et al) (Letter); (Nozawa) (Reply). 1990;163:698-9
Lectins and heparin-binding features of human spermatozoa as analyzed by flow cytometry (Vasquez et al). 1990;163:2006-12

Flowmeters
Assessment of cerebral hemodynamics in pregnant women by internal carotid artery pulsed Doppler velocimetry (Ikeda and Mori). 1990;163:494-8
Color flow Doppler—a useful instrument in the diagnosis of vasa previa (Harding et al). 1990;163:1566-8
The diagnostic values of concurrent nonstress testing, amniotic fluid measurement, and Doppler velocimetry in screening a general high-risk population (Devoe et al). 1990;163:1040-8
Ductus arteriosus flow velocity modulation by fetal breathing movements as a measure of fetal lung development (van Eyck et al). 1990;163:558-66
The effect of nifedipine therapy on fetal and placental Doppler waveforms in preeclampsia remote from term (Moretti et al). 1990;163:1844-8
Effect of tocolytic agents on fetal umbilical velocimetry (Wright et al). 1990;163:748-50
Fetal Doppler velocimetry in twins (Degani) (Letter); (Divon) (Reply). 1990;163:1100-1
Fetal umbilical artery Doppler response to graded maternal aerobic exercise and subsequent maternal mean arterial blood pressure: predictive value for pregnancy-induced hypertension (Hume et al). 1990;163:826-9
Prenatal diagnosis of a chest wall mass with ultrasonography and Doppler velocimetry: a case report (Smith et al). 1990;163:567-9
Variation and correlation in human fetal umbilical Doppler velocities with fetal breathing: evidence of the cardiac-placental connection (Indik and Reed). 1990;163:1792-6

Fluorouracil
5-Fluorouracil exposure during the period of conception: report on two cases (Odom et al). 1990;163:76-7

Focal migraine; *see* **Migraine**

Follicle, Graafian; *see* **Graafian follicle**

Follicle stimulating hormone; *see* **FSH**

Forceps, obstetrical; *see* **Obstetrical forceps**

Foreign bodies
A vesicovaginal fistula and intravesical foreign body: a rare case of the neglected pessary (Goldstein et al). 1990;163:589-91

FSH
The luteinizing hormone–releasing hormone pulse generator in men: abnormalities and clinical management (Matsumoto et al). 1990;163:1743-51 (Supplement)
Relationship between plasma calcium fractions, other bone-related variables, and serum follicle-stimulating hormone levels in premenopausal, perimenopausal, and postmenopausal women (Nordin et al). 1990;163:140-5

5-FU; *see* **Fluorouracil**

G

Gastrointestinal diseases
Gastrointestinal disease and oral contraception (Hanker). 1990;163:2204-7 (Symposium)

Gastroschisis; *see* **Abdominal wall**

Gastrula
Embryopathic effects of short-term exposure to hypoglycemia in mouse embryos in vitro (Smoak and Sadler). 1990;163:619-24

Genetic screening
Appropriate screening tests (Nagey) (Letter); (Chervenak et al) (Reply). 1990;163:688-9
Genetics
Sharing of human leukocyte antigens in primary and secondary recurrent spontaneous abortions (Ho et al). 1990;163:178-88
Genital neoplasms, female
The Maylard incision in gynecologic cancer (Helmkamp and Krebs). 1990;163:1554-7
Genome, human
Isolation and characterization of the gene from a human genome encoding 17β-estradiol dehydrogenase: a comparison of Jar and BeWo choriocarcinoma cell lines (Long et al). 1990;163:1976-81
Gestagens; *see* **Sex hormones**
Gestational age
Reliability of ultrasonographic formulary in the prediction of fetal weight and survival of very-low-birth-weight infants (Mills et al). 1990;163:1568-74
Ultrasonographic dating of very early pregnancy (Cadkin and McAlpin-Cadkin). 1990;163:1103 (Letter)
Ultrasonographic fetal weight estimation by an integrated computer-assisted system: Can each laboratory improve its accuracy? (Thompson et al). 1990;163:986-95
Gestational diabetes; *see* **Pregnancy in diabetes**
Gestodene
Binding of oral contraceptive progestogens to serum proteins and cytoplasmic receptor (Juchem and Pollow). 1990;163:2171-83 (Symposium)
Clinical acceptability of monophasic gestodene (Düsterberg and Brill). 1990;163:1398-403 (Supplement)
Inhibition of oral contraceptive steroid-metabolizing enzymes by steroids and drugs (Guengerich). 1990;163:2159-63 (Symposium)
Inhibition of ovulation by low-dose monophasic contraceptive containing gestodene (Thomas and Vankrieken). 1990;163:1404-9 (Supplement)
Pharmacokinetics and pharmacodynamics of oral contraceptive steroids: factors influencing steroid metabolism (Jung-Hoffmann and Kuhl). 1990;163:2183-97 (Symposium)
Pharmacokinetics of gestodene and ethinyl estradiol after oral administration of a monophasic contraceptive (Täuber et al). 1990;163:1414-20 (Supplement)
Pharmacokinetics of the contraceptive steroids levonorgestrel and gestodene after single and multiple oral administration to women (Kuhnz). 1990;163:2120-7 (Symposium)
Gestodene/ethinyl estradiol
Comparative studies of 30 μg ethinyl estradiol combined with gestodene and desogestrel on blood coagulation, fibrinolysis, and platelets (Daly and Bonnar). 1990;163:430-7 (Supplement)
Effects of long-term gestodene-containing oral contraceptive administration on hemostasis (Abbate et al). 1990;163:424-9 (Supplement)
Effects of newer oral contraceptives on the inhibition of coagulation and fibrinolysis in relation to dosage and type of steroid (Jespersen et al). 1990;163:396-403 (Supplement)
Estrogenic effect of gestodene- or desogestrel-containing oral contraceptives on lipoprotein metabolism (Gevers Leuven et al). 1990;163:358-62 (Supplement)
Metabolic changes during treatment with two different progestogens (Refn et al). 1990;163:374-7 (Supplement)
Protein binding of active ingredients and comparison of serum ethinyl estradiol sex hormone–binding globulin, corticosteroid-binding globulin, and cortisol levels in women using a combination of gestodene/ethinyl estradiol (Femovan) or a combination of desogestrel/ethinyl estradiol (Marvelon) and single-dose ethinyl estradiol bioequivalence from both oral contraceptives (Hümpel et al). 1990;163:329-33 (Supplement)
Time-dependent alterations in lipid metabolism during treatment with low-dose oral contraceptives (Kuhl et al). 1990;163:363-9 (Supplement)
Gittes procedure; *see* **Suspensions**
Glucose
Amniotic fluid glucose concentration: a rapid and simple method for the detection of intraamniotic infection in preterm labor (Romero et al). 1990;163:968-74
Mechanism of action of oral contraceptives on carbohydrate metabolism at the cellular level (Skouby et al). 1990;163:343-8 (Supplement)
Response of placental vasculature to high glucose levels in the isolated human placental cotyledon (Roth et al). 1990;163:1828-30
Glucose tolerance test
Does fasting interval affect the glucose challenge test? (Berkus et al). 1990;163:1812-7
Effect of low-dose oral contraceptives on carbohydrate and lipid metabolism in women with recent gestational diabetes: results of a controlled, randomized, prospective study (Kjos et al). 1990;163:1822-7
Effects of ethinyl estradiol combined with desogestrel and cyproterone acetate on glucose tolerance and insulin response to an oral glucose load: a one-year randomized, prospective, comparative trial (Jandrain et al). 1990;163:378-81 (Supplement)
Gestational diabetes mellitus: the prevalence of glucose intolerance and diabetes mellitus in the first two months post partum (Kjos et al). 1990;163:93-8
Glucose tolerance in pregnancy: ethnic variation and influence of body habitus (Green et al). 1990;163:86-92
Impairment of glucose tolerance: mechanism of action and impact on the cardiovascular system (Beck-Nielsen et al). 1990;163:292-5 (Supplement)
Low-dose oral contraceptives and carbohydrate metabolism (Godsland et al). 1990;163:348-53 (Supplement)
Relationships between glucose levels and insulin secretion during a glucose challenge test (Berkus et al). 1990;163:1818-21
Glycoprotein hormones, alpha subunit
Stability of human chorionic gonadotropin and its α-subunit (Rao et al). 1990;163:1098-9 (Letter)
Glycoproteins
Epithelial cells from normal human endometrium express a tumor-associated glycoprotein (TAG-72) epitope in vitro (Osteen et al). 1990;163:479-84
Expression of P-glycoprotein in epithelial ovarian cancer: evaluation as a marker of multidrug resistance (Rubin et al). 1990;163:69-73
Glycosylation
Comparisons of glycosylated and nonglycosylated amniotic fluid prolactins in normal second- and third-trimester pregnancies (McCoshen et al). 1990;163:81-5
GnRH; *see* **Pituitary hormone releasing hormones**
Gonadal dysgenesis
Correlation of the testicular determinant factor sequence zinc finger Y with varying gonadal phenotypes in a series

of 13 subjects with gonadal dysgenesis because of Y aneuploidy (Tho et al). 1990;163:1968-75

Gonadotropin releasing hormone agonists; *see* **Pituitary hormone release inhibiting hormones**

Gonadotropin releasing hormones; *see* **Pituitary hormone releasing hormones**

Gonadotropins, chorionic

Corpus luteum function in early pregnancies is primarily determined by the rate of change of human chorionic gonadotropin levels (Kratzer and Taylor). 1990;163:1497-502

Maternal serum Down syndrome screening: free β-protein is a more effective marker than human chorionic gonadotropin (Macri et al). 1990;163:1248-53

Measures of test performance and predictive values (Kadar) (Letter); (Schiff et al) (Reply). 1990;163:1374-5

Use of serial human chorionic gonadotropin measurements to differentiate between intrauterine and ectopic pregnancies (Kadar) (Letter); (Lindblom et al) (Reply). 1990;163:259-61

Graafian follicle

Oxytocin and vasopressin binding sites in human and bovine ovaries (Fuchs et al). 1990;163:1961-7

Gram stain; *see* **Stains and staining**

Granulosa cell tumor

Large cystic granulosa cell tumor: case report (Choi and Pritchard). 1990;163:74-6

Granulosa cell tumor, animal

Ovarian granulosa cell tumorigenesis in SWR-derived F1 hybrid mice: preneoplastic follicular abnormality and malignant disease progression (Tennent et al). 1990;163:625-34

Group B streptococcus; *see* ***Streptococcus agalactiae***

Growth factors; *see* **Growth substances**

Growth retardation, intrauterine; *see* **Fetal growth retardation**

Growth substances

Growth factor activity in the blood of women in whom preeclampsia develops is elevated from early pregnancy (Taylor et al). 1990;163:1839-44

Preferential mitogenic activity for myoblast-like cells can be extracted from uterine leiomyoma tissues (Koutsilieris et al). 1990;163:1665-70

Gynecologic procedures; *see* **Surgery, operative**

H

Habitual abortion; *see* **Abortion, habitual**

HBsAg; *see* **Hepatitis B surface antigens**

Heart defects, congenital

Accuracy of apical four-chamber view as screen for congenital heart disease (Stephens). 1990;163:249-50 (Letter)

Heart failure, congestive

In utero detection of cardiac failure from an aneurysm of the vein of Galen (Jeanty et al). 1990;163:50-1

Heart rate, fetal

Effects of hypertension on pregnancy monitoring and results (Lenox et al). 1990;163:1173-9

Effects of intravascular fetal blood transfusion on fetal intracardiac Doppler velocity waveforms (Rizzo et al). 1990;163:1231-8

Fetal heart rate monitoring during cesarean section (Dunn) (Letter); (Petrikovsky et al) (Reply). 1990;163:253

Graphic mnemonic for variable decelerations (Chao). 1990;163:1098 (Letter)

Sinusoidal fetal heart rate pattern during cardiopulmonary bypass (Burke et al). 1990;163:17-8

Sources of variability in umbilical artery systolic/diastolic ratios: implications of Poiseuille equation (Wright and Ridgway). 1990;163:1788-91

Vibroacoustic stimulation and fetal behavioral state in normal term human pregnancy (Devoe et al). 1990;163:1156-61

Heart rate, fetal, animal

Role of vasopressin in mediation of fetal cardiovascular responses to acute hypoxia (Piacquadio et al). 1990;163:1294-300

Heart septum

Human fetal foramen ovale flow velocity waveforms relative to behavioral states in normal term pregnancy (van Eyck et al). 1990;163:1239-42

Heart transplantation

Postpartum coronary artery dissection followed by heart transplantation (Curiel et al). 1990;163:538-9

Heart valve prosthesis

Effect of mitral valve prosthetic surgery on the outcome of a growth-retarded fetus: a case report (Izquierdo et al). 1990;163:584-7

Heart ventricle, animal

Nifedipine enhances the cardiac toxicity of magnesium sulfate in the isolated perfused Sprague-Dawley rat heart (Thorp et al). 1990;163:655-6

HELLP syndrome; *see* **Pregnancy complications, hematologic**

Hemangioma

Prenatal diagnosis of a chest wall mass with ultrasonography and Doppler velocimetry: a case report (Smith et al). 1990;163:567-9

Spontaneous infarction of placental chorioangioma and associated regression of hydrops fetalis (Chazotte et al). 1990;163:1180-1

Hemodynamics

Acute fetal hemodynamic alterations after intrauterine transfusion for treatment of severe red cell alloimmunization (Moise et al). 1990;163:776-84

Assessment of cerebral hemodynamics in pregnant women by internal carotid artery pulsed Doppler velocimetry (Ikeda and Mori). 1990;163:494-8

Maternal and uteroplacental hemodynamic effects of chronic captopril in the hypertensive, term-pregnant rat (Mabie et al). 1990;163:1861-7

Hemoglobin A, glycosylated

Maternal serum α-fetoprotein levels in pregnancies complicated by diabetes: implications for screening programs (Martin et al). 1990;163:1209-16

Hemoglobins

Discrepancies in hemoglobin levels (Giles et al). 1990;163:1713 (Letter)

Hemolytic disease of newborn; *see* **Erythroblastosis, fetal**

Hemoperitoneum

Hemoperitoneum as a result of coital injury without associated vaginal injury (McColgin et al). 1990;163:1503-5

Hemorrhage

A comment on thumbtacks for hemorrhage control (Mann) (Letter); (Patsner) (Reply). 1990;163:1092-3

Hyperadrenergic orthostatic intolerance as a result of postpartum blood loss (Mader et al). 1990;163:1578-9

A reappraisal of the need for autologous blood donation in the obstetric patient (Andres et al). 1990;163:1551-3

Hemostasis
Clinical aspects of the relationship between oral contraceptives and abnormalities of the hemostatic system: relation to the development of cardiovascular disease (Kelleher). 1990;163:392-5 (Supplement)
A comment on thumbtacks for hemorrhage control (Mann) (Letter); (Patsner) (Reply). 1990;163:1092-3
Hemostasis profile in women taking low-dose oral contraceptives (David et al). 1990;163:420-3 (Supplement)
Interrelations between carbohydrates, lipids, and the hemostatic system in relation to the risk of thrombotic and cardiovascular disease (Juhan-Vague and Vague). 1990;163:313-5 (Supplement)
Oral contraceptives in risk groups: Exclusion or monitoring? (Guillebaud). 1990;163:443-6 (Supplement)
Hemostatic system disorders; *see* **Blood coagulation disorders**
Heparin
Lectins and heparin-binding features of human spermatozoa as analyzed by flow cytometry (Vasquez et al). 1990;163:2006-12
Hepatitis B
Intrapartum hepatitis B screening in a low-risk population (Ernest et al). 1990;163:978-80
Hepatitis B surface antigens
HBcAg identification in the placental cytotypes of symptom-free HBsAg-carrier mothers: a study with the immunoperoxidase method (Lucifora et al). 1990;163:235-9
Intrapartum hepatitis B screening in a low-risk population (Ernest et al). 1990;163:978-80
Hepatocytes; *see* **Liver**
Hepatolenticular degeneration
Pregnancy in a patient with treated Wilson's disease: a case report (Dupont et al). 1990;163:1527-8
Hernia, umbilical
The associated anomalies that determine prognosis in congenital omphaloceles (Tucci and Bard). 1990;163:1646-9
Fetal gastroschisis and omphalocele: Is cesarean section the best mode of delivery? (Lewis et al). 1990;163:773-5
Heterotopic pregnancy; *see* **Pregnancy, ectopic**
Hippel-Lindau disease
Papillary cystadenoma of the broad ligament in von Hippel-Lindau disease (Korn et al). 1990;163:596-8
Hirsutism
Evidence of heterogeneous mechanisms in lipoprotein lipid alterations in hyperandrogenic women (Wild et al). 1990;163:1998-2005
Histamine
Studies of the spontaneous motility and the effect of histamine on isolated myometrial strips of the nonpregnant human uterus: the influence of various uterine abnormalities (Martinez-Mir et al). 1990;163:189-95
HIV
Pregnancy outcomes among mothers infected with human immunodeficiency virus and uninfected control subjects (Minkoff et al). 1990;163:1598-604
The relationship of cocaine use to syphilis and human immunodeficiency virus infections among inner city parturient women (Minkoff et al). 1990;163:521-6
Risk factors associated with the increasing prevalence of pneumonia during pregnancy (Berkowitz and LaSala). 1990;163:981-5
Vulvar ulcer of unknown etiology in a human immunodeficiency virus–infected woman: response to treatment with zidovudine (Covino and McCormack). 1990;163:116-8
HIV infections
Drug prophylaxis for human immunodeficiency virus–infected pregnant women: ethical considerations (Minkoff and Moreno). 1990;163:1111-4 (Clin. opinion)
Sexually transmitted diseases and human immunodeficiency virus infection among women with pelvic inflammatory disease (Hoegsberg et al). 1990;163:1135-9
HLA antigens
Sharing of human leukocyte antigens in primary and secondary recurrent spontaneous abortions (Ho et al). 1990;163:178-88
HLA-DR1 antigen
Interleukin-1β, human leukocyte antigen DR1, and transforming growth factor-β expression in endometrium, placenta, and placental membranes (Kauma et al). 1990;163:1430-7
Hormone–binding globulin
Serum pharmacokinetics of orally administered desogestrel and binding of contraceptive progestogens to sex hormone–binding globulin (Bergink et al). 1990;163:2132-7 (Symposium)
Human chorionic gonadotropin; *see* **Gonadotropins, chorionic**
Human chorionic gonadotropin, alpha subunit; *see* **Glycoprotein hormones, alpha subunit**
Human immunodeficiency virus; *see* **HIV**
Human leukocyte antigen; *see* **HLA antigens**
Human leukocyte antigen DR1; *see* **HLA-DR1 antigen**
Hybridization
Preembryo biopsy and analysis of blastomeres by in situ hybridization (Grifo et al). 1990;163:2013-9
The use of in situ hybridization to show human papillomavirus deoxyribonucleic acid in metastatic cancer cells within lymph nodes (Lewandowski et al). 1990;163:1333-7
Hydatidiform mole
Differential diagnosis between complete mole and hydropic abortus by deoxyribonucleic acid fingerprints (Nobunaga et al). 1990;163:634-8
Discrepancy in the diagnoses of hydatidiform mole by macroscopic and microscopic findings and the deoxyribonucleic acid fingerprint method (Takahashi et al). 1990;163:112-3
Hydramnios
Indomethacin treatment for polyhydramnios and subsequent infantile nephrogenic diabetes insipidus (Smith et al). 1990;163:98-9
Observations on the cause of oligohydramnios in prolonged pregnancy (Trimmer et al). 1990;163:1900-3
The stuck twin phenomenon: Ultrasonographic findings, pregnancy outcome, and management with serial amniocenteses (Mahony et al). 1990;163:1513-22
Superiority of the four-quadrant sum over the single-deepest-pocket technique in ultrasonographic identification of abnormal amniotic fluid volumes (Moore). 1990;163:762-7
Twin-twin transfusion syndrome (Urig et al). 1990;163:1522-6
Hydramnios, animal
A mechanism leading to reduced lung expansion and lung hypoplasia in fetal sheep during oligohydramnios (Harding et al). 1990;163:1904-13

Hydrocortisone
Protein binding of active ingredients and comparison of serum ethinyl estradiol sex hormone–binding globulin, corticosteroid-binding globulin, and cortisol levels in women using a combination of gestodene/ethinyl estradiol (Femovan) or a combination of desogestrel/ethinyl estradiol (Marvelon) and single-dose ethinyl estradiol bioequivalence from both oral contraceptives (Hümpel et al). 1990;163:329-33 (Supplement)
Hydrogen-ion concentration
Comparison of umbilical artery pH and 5-minute Apgar score in the low-birth-weight and very-low-birth-weight infant (Stark et al). 1990;163:818-23
Hydropic abortus; *see* **Hydrops fetalis**
Hydrops, nonimmune; *see* **Edema**
Hydrops fetalis
Differential diagnosis between complete mole and hydropic abortus by deoxyribonucleic acid fingerprints (Nobunaga et al). 1990;163:634-8
Management and outcomes of pregnancies complicated by human B19 parvovirus infection: a prospective study (Rodis et al). 1990;163:1168-71
Niemann-Pick disease associated with nonimmune hydrops fetalis (Meizner et al). 1990;163:128-9
Placental transfer of cefazolin and piperacillin in pregnancies remote from term complicated by Rh isoimmunization (Brown et al). 1990;163:938-43
Prenatal diagnosis of laryngeal atresia (Watson et al). 1990;163:1456-7
Prognostic indicators of the resolution of nonimmune hydrops fetalis and survival of the fetus (Carlson et al). 1990;163:1785-7
Spontaneous infarction of placental chorioangioma and associated regression of hydrops fetalis (Chazotte et al). 1990;163:1180-1
Survival in a fetus with sacrococcygeal teratoma and hydrops (Nakayama). 1990;163:682 (Letter)
Hydroxyprostaglandin dehydrogenases
Immunocytochemical distribution and localization of 15-hydroxyprostaglandin dehydrogenase in human fetal membranes, decidua, and placenta (Cheung et al). 1990;163:1445-9
Hygroma, cystic; *see* **Lymphangioma**
Hygroscopic cervical dilators; *see* **Surgical instruments**
Hyperandrogenism; *see* **Hirsutism**
Hyperbaric oxygenation
Hyperbaric oxygen therapy for air embolism complicating operative hysteroscopy (Tur-Kaspa) (Letter); (Baggish) (Reply). 1990;163:680-1
Hyperimmunoglobulinemia; *see* **Immunoglobulins**
Hyperkalemia
Hyperkalemia secondary to irradiation of packed red blood cells: possible effects with intravascular fetal transfusion (Thorp et al). 1990;163:607-9
Hypertension
Epidemiology of preeclampsia and eclampsia in the United States, 1979-1986 (Saftlas et al). 1990;163:460-5
Fetal and maternal response to intravenous infusion of a thromboxane synthetase inhibitor (Cardin et al). 1990;163:1345-9
Fetal umbilical artery Doppler response to graded maternal aerobic exercise and subsequent maternal mean arterial blood pressure: predictive value for pregnancy-induced hypertension (Hume et al). 1990;163:826-9
Intracellular sodium levels in pregnant women with hypertension (Goodlin) (Letter); (Sowers and Zemel) (Reply). 1990;163:261-2
Laboratory identification of the lupus anticoagulant in normal pregnancy and pregnancy-induced hypertension (Riveros et al) (Letter); (Lockwood) (Reply). 1990;163:704-5
Longitudinal study of the renin-angiotensin-aldosterone system in hypertensive pregnant women: deviations related to the development of superimposed preeclampsia (August et al). 1990;163:1612-21
National High Blood Pressure Education Program Working Group report on high blood pressure in pregnancy. 1990;163:1691-712 (Supplement)
National High Blood Pressure Education Program Working Group report on high blood pressure in pregnancy: foreword (Lenfant et al). 1990;163:1689-90 (Supplement)
The natural history of thrombocytopenia associated with preeclampsia (Katz et al). 1990;163:1142-3
Oral contraception in disease states (Breckwoldt et al). 1990;163:2213-6 (Symposium)
Hypertension, animal
Hypoxic acidemia, hyperviscosity, and maternal hypertension do not affect the umbilical arterial velocity waveform in fetal sheep (Morrow et al). 1990;163:1313-20
Maternal and uteroplacental hemodynamic effects of chronic captopril in the hypertensive, term-pregnant rat (Mabie et al). 1990;163:1861-7
Hyperviscosity, animal; *see* **Blood viscosity, animal**
Hypoglycemia, animal
Embryopathic effects of short-term exposure to hypoglycemia in mouse embryos in vitro (Smoak and Sadler). 1990;163:619-24
Hypogonadism
Gonadotropin-releasing hormone deficiency in men: diagnosis and treatment with exogenous gonadotropin-releasing hormone (Crowley and Whitcomb). 1990;163:1752-8 (Supplement)
Hypotension
Effect of uterine contractility and maternal hypotension on prolonged decelerations after bupivacaine epidural anesthesia (Steiger and Nageotte). 1990;163:808-12
Hypotension, animal
Magnesium sulfate and promethazine do not interact to cause hypotension in gravid ewes (Pollack et al). 1990;163:787-94
Hypotension, orthostatic
Hyperadrenergic orthostatic intolerance as a result of postpartum blood loss (Mader et al). 1990;163:1578-9
Hypothalamus
Parameters of hypothalamic aging (Seifer and Jones) (Letter); (Alexander and Aksel) (Reply). 1990;163:1715
Hypothyroidism
Early hypothyroidism in patients with menorrhagia (Blesing and Hambley) (Letter); (Wilansky and Greisman) (Reply). 1990;163:697
Screening infertile women for subclinical hypothyroidism (Strickland et al) (Letter); (Wilansky and Greisman) (Reply). 1990;163:262-3
Hypoxia; *see* **Anoxia**
Hypoxia, fetal; *see* **Fetal anoxia**
Hyskon, adverse effects
Explanation of mechanism of Hyskon solution reaction needed (Loffer). 1990;163:2029 (Letter)
Hysterectomy
Bacterial vaginosis and trichomoniasis vaginitis are risk fac-

Hysterectomy—cont'd
tors for cuff cellulitis after abdominal hysterectomy (Soper et al). 1990;163:1016-23
Experience with the EndoPap device for the cytologic detection of uterine cancer and its precursors: a comparison of the EndoPap with fractional curettage or hysterectomy (LaPolla et al). 1990;163:1055-60
The impact of a quality assurance process on the frequency and confirmation rate of hysterectomy (Gambone et al). 1990;163:545-50
Hysteroscopy
Hyperbaric oxygen therapy for air embolism complicating operative hysteroscopy (Tur-Kaspa) (Letter); (Baggish) (Reply). 1990;163:680-1
Safety of 32% dextran 70 for hysteroscopy (Ljungström) (Letter); (Jedeikin and Olsfanger) (Reply). 1990;163:2029-30
Hysteroscopy, animal
A rabbit model for bacteria-induced preterm pregnancy loss (Dombroski et al). 1990;163:1938-43

I

Idiopathic hypogonadotropic hypogonadism; *see* **Hypogonadism**
Idiopathic thrombocytopenia purpura; *see* **Purpura, thrombocytopenic**
IgG
Immunoglobulin G fractions from patients with antiphospholipid antibodies cause fetal death in BALB/c mice: a model for autoimmune fetal loss (Branch et al). 1990;163:210-6
Immune globulin; *see* **Immunization, passive**
Immune sera
A case of Rh isoimmunization: Should threatened first-trimester abortion be an indication for Rh immune globulin prophylaxis? (Dayton et al). 1990;163:63-4
Immunity, cellular
Lymphocyte proliferative response to fertilization antigen in patients with antisperm antibodies (Naz et al). 1990;163:610-3
Immunization, passive
A case of Rh isoimmunization: Should threatened first-trimester abortion be an indication for Rh immune globulin prophylaxis? (Dayton et al). 1990;163:63-4
Postinjection kinetics of antepartum Rh immune globulin (Witter et al). 1990;163:784-6
Immunoassay
A comparison of sperm antibody assays (Daru and Mathur). 1990;163:1622-9
Immunocontraception; *see* **Contraception, immunologic**
Immunocyte chemistry; *see* **Immunohistochemistry**
Immunoenzyme techniques
Comparison of a rapid enzyme-linked immunosorbent assay test and the Gram stain for detection of group B streptococcus in high-risk antepartum patients (Towers et al). 1990;163:965-7
HBcAg identification in the placental cytotypes of symptom-free HBsAg-carrier mothers: a study with the immunoperoxidase method (Lucifora et al). 1990;163:235-9
Immunoglobulin G; *see* **IgG**
Immunoglobulins
Continuing controversy in alloimmune thrombocytopenia: fetal hyperimmunoglobulinemia fails to prevent thrombocytopenia (Nicolini et al). 1990;163:1144-6
Immunohistochemistry
Immunocytochemical distribution and localization of 15-hydroxyprostaglandin dehydrogenase in human fetal membranes, decidua, and placenta (Cheung et al). 1990;163:1445-9
Uterine artery estrogen receptors in the nonpregnant and pregnant guinea pig (Leiberman et al). 1990;163:1685-8
Immunoperoxidase methods; *see* **Immunoenzyme techniques**
Immunosuppression
Soluble factors produced by isolated first-trimester chorionic villi directly inhibit proliferation of T cells (Silver et al). 1990;163:1914-9
Impedance cardiography; *see* **Cardiography, impedance**
In situ hybridization; *see* **Hybridization**
In vitro fertilization; *see* **Fertilization in vitro**
Incisions; *see* **Surgery, operative**
Incontinence, urinary, stress; *see* **Urinary incontinence, stress**
Indomethacin
Indomethacin treatment for polyhydramnios and subsequent infantile nephrogenic diabetes insipidus (Smith et al). 1990;163:98-9
Venous and hepatic vascular responses to indomethacin and prostaglandin E_1 in the fetal lamb (Paulick et al). 1990;163:1357-63
Induced labor; *see* **Labor, induced**
Infant, low birth weight
Comparison of umbilical artery pH and 5-minute Apgar score in the low-birth-weight and very-low-birth-weight infant (Stark et al). 1990;163:818-23
The effect of physical activity during pregnancy on preterm delivery and birth weight (Klebanoff et al). 1990;163:1450-6
Mortality rates ignore population segment (Harkavy) (Letter); (Resnick and Ariet) (Reply). 1990;163:269-70
The perinatal impact of cocaine, amphetamine, and opiate use detected by universal intrapartum screening (Gillogley et al). 1990;163:1535-42
Prognosis for twins with birth weight <1500 gm: the impact of cesarean section in relation to fetal presentation (Rydhström). 1990;163:528-33
Reliability of ultrasonographic formulary in the prediction of fetal weight and survival of very-low-birth-weight infants (Mills et al). 1990;163:1568-74
Survival and outcome of infants weighing <800 grams at birth (Lipper et al). 1990;163:146-50
Infant, newborn
The association of intrapartum asphyxia in the mature fetus with newborn behavior (Low et al). 1990;163:1131-5
Correlations between antepartum maternal metabolism and newborn behavior (Rizzo et al). 1990;163:1458-64
Insulin-like growth factor II and nonsuppressible insulin-like activity levels in newborns (Samaan et al). 1990;163:1836-9
Infant, newborn, diseases
Comparison of a rapid enzyme-linked immunosorbent assay test and the Gram stain for detection of group B streptococcus in high-risk antepartum patients (Towers et al). 1990;163:965-7
Cost-effectiveness of intrapartum screening and treatment for maternal group B streptococci colonization (Strickland et al). 1990;163:4-8 (Clin. opinion)
The differential neonatal morbidity of the intrauterine growth retardation syndrome (Villar et al). 1990;163:151-7
Digoxin-like immunoreactive factor and respiratory distress syndrome (Goodlin). 1990;163:1091 (Letter)

In utero detection of cardiac failure from an aneurysm of the vein of Galen (Jeanty et al). 1990;163:50-1
Indomethacin treatment for polyhydramnios and subsequent infantile nephrogenic diabetes insipidus (Smith et al). 1990;163:98-9

Infant, premature
Amniotic fluid glucose concentration: a rapid and simple method for the detection of intraamniotic infection in preterm labor (Romero et al). 1990;163:968-74
Antenatal microbiologic and maternal risk factors associated with prematurity (McGregor et al). 1990;163:1465-73
Calcium supplementation during pregnancy may reduce preterm delivery in high-risk populations (Villar and Repke). 1990;163:1124-31
Cervicovaginal microflora and pregnancy outcome: results of a double-blind, placebo-controlled trial of erythromycin treatment (McGregor et al). 1990;163:1580-91
Evaluation of a risk scoring system as a predictor of preterm birth in an indigent population (Owen et al). 1990;163:873-9
Reliability of ultrasonographic formulary in the prediction of fetal weight and survival of very-low-birth-weight infants (Mills et al). 1990;163:1568-74
Risk factors for preterm premature rupture of fetal membranes: a multicenter case-control study (Harger et al). 1990;163:130-7

Infant behavior; *see* **Behavior, infant**

Infant mortality
A chill wind blows: Webster, obstetrics, and the health of women (Chavkin and Rosenfield). 1990;163:450-2 (Clin. opinion)
Mortality rates ignore population segment (Harkavy) (Letter); (Resnick and Ariet) (Reply). 1990;163:269-70
Perinatal mortality in Victoria, Australia: role of group B streptococcus (Fliegner and Garland). 1990;163:1609-11
Preeclampsia in diabetic pregnancies (Garner et al). 1990;163:505-8
Prognosis for twins with birth weight <1500 gm: the impact of cesarean section in relation to fetal presentation (Rydhström). 1990;163:528-33
Survival rates of monoamniotic twins do not decrease after 30 weeks' gestation (Carr et al). 1990;163:719-22

Infarction
The association of maternal floor infarction of the placenta with adverse perinatal outcome (Andres et al). 1990;163:935-8

Infection
Gram stain results from amniocentesis in patients with preterm permature rupture of membranes—comparison of maternal and fetal characteristics (Asrat et al). 1990;163:887-9
HBcAg identification in the placental cytotypes of symptom-free HBsAg-carrier mothers: a study with the immunoperoxidase method (Lucifora et al). 1990;163:235-9
Infection and labor. VI. Prevalence, microbiology, and clinical significance of intraamniotic infection in twin gestations with preterm labor (Romero et al). 1990;163:757-61
Preterm delivery: a risk factor for retained placenta (Romero et al). 1990;163:823-5

Infection, animal
A rabbit model for bacteria-induced preterm pregnancy loss (Dombroski et al). 1990;163:1938-43

Infection, congenital
Prenatal diagnosis of congenital cytomegalovirus infection: two decades later (Grose and Weiner). 1990;163:447-50 (Clin. opinion)

Infertility, female
Antisperm antibodies in women undergoing intrauterine insemination (Goldberg et al). 1990;163:65-8
Association between autoantibodies and unexplained infertility unproved (Maier) (Letter); (Taylor and Campbell) (Reply). 1990;163:243
Human oocyte and preembryo donation: an evolving method for the treatment of infertility (Sauer and Paulson). 1990;163:1421-4 (Clin. opinion)
Infertility and eating disorders (Stewart et al). 1990;163:1196-9
Screening infertile women for subclinical hypothyroidism (Strickland et al) (Letter); (Wilansky and Greisman) (Reply). 1990;163:262-3
The use of serial CA 125 concentrations to monitor endometriosis in infertile women (Pittaway). 1990;163:1032-7

Infertility, male
A comparison of sperm antibody assays (Daru and Mathur). 1990;163:1622-9

Inflammatory bowel disease
Intrapartum uterine rupture and inflammatory bowel disease (Peterson and Braak). 1990;163:1247-8

Informed consent
Drug prophylaxis for human immunodeficiency virus–infected pregnant women: ethical considerations (Minkoff and Moreno). 1990;163:1111-4 (Clin. opinion)

Insemination, artificial
Antisperm antibodies in women undergoing intrauterine insemination (Goldberg et al). 1990;163:65-8

Instruments, surgical; *see* **Surgical instruments**

Insulin
Does fasting interval affect the glucose challenge test? (Berkus et al). 1990;163:1812-7
Effects of ethinyl estradiol combined with desogestrel and cyproterone acetate on glucose tolerance and insulin response to an oral glucose load: a one-year randomized, prospective, comparative trial (Jandrain et al). 1990;163:378-81 (Supplement)
Infants of diabetic mothers with accelerated fetal growth by ultrasonography: Are they all alike? (Keller et al). 1990;163:893-7
Interrelations between carbohydrates, lipids, and the hemostatic system in relation to the risk of thrombotic and cardiovascular disease (Juhan-Vague and Vague). 1990;163:313-5 (Supplement)
Long-term maternal-fetal exposure to high-low insulin concentrations alter liver but not brain insulin receptors (Devaskar et al). 1990;163:1350-6
Low-dose oral contraceptives and carbohydrate metabolism (Godsland et al). 1990;163:348-53 (Supplement)
Relationships between glucose levels and insulin secretion during a glucose challenge test (Berkus et al). 1990;163:1818-21
Suppression of serum insulin level by diazoxide does not alter serum testosterone of sex hormone–binding globulin levels in healthy, nonobese women (Nestler et al). 1990;163:1243-6

Insulin-dependent diabetes; *see* **Pregnancy in diabetes**

Insulin-like growth factor I
Specific binding sites for insulin-like growth factor I in the ovarian stroma of women with polycystic ovarian disease and stromal hyperthecosis (Nagamani and Stuart). 1990;163:1992-7

Insulin-like growth factor II
Insulin-like growth factor II and nonsuppressible insulin-like activity levels in newborns (Samaan et al). 1990;163:1836-9
Insulin resistance
Diabetic ketoacidosis and insulin resistance with subcutaneous terbutaline infusion: a case report (Tibaldi et al). 1990;163:509-10
Effects of oral contraceptives on carbohydrate and lipid metabolisms in a healthy population: the Telecom Study (Simon et al). 1990;163:382-7 (Supplement)
Impairment of glucose tolerance: mechanism of action and impact on the cardiovascular system (Beck-Nielsen et al). 1990;163:292-5 (Supplement)
Mechanism of action of oral contraceptives on carbohydrate metabolism at the cellular level (Skouby et al). 1990;163:343-8 (Supplement)
Intensive care, neonatal
Mortality rates ignore population segment (Harkavy) (Letter); (Resnick and Ariet) (Reply). 1990;163:269-70
Survival and outcome of infants weighing <800 grams at birth (Lipper et al). 1990;163:146-50
Interferon-γ; *see* **Interferon type II**
Interferon type II
Proliferative and antiproliferative effects of interferon-γ and tumor necrosis factor-α on cell lines derived from cervical and ovarian malignancies (Mutch et al). 1990;163:1920-4
Interleukin-1
Mechanism of action of interleukin-1β in increasing corticotropin-releasing factor and adrenocorticotropin hormone release from cultured human placental cells (Petraglia et al). 1990;163:1307-12
Interleukin-2
Lymphokine production during term human pregnancy: differences between peripheral leukocytes and decidual cells (Dudley et al). 1990;163:1890-3
Serum levels of interleukin-2 and tumor necrosis factor α in women with recurrent abortion (Mallmann et al). 1990;163:1367 (Letter)
Interleukins
Interleukin-1β, human leukocyte antigen DR1, and transforming growth factor-β expression in endometrium, placenta, and placental membranes (Kauma et al). 1990;163:1430-7
Internal carotid artery; *see* **Carotid artery, internal**
Internship and residency
Does obstetric ethics have any role in the obstetrician's response to the abortion controversy? (Chervenak and McCullough). 1990;163:1425-9 (Clin. opinion)
Intraamniotic infection; *see* **Amniotic fluid**; **Chorioamnionitis**
Intracellular fluid
Intracellular sodium levels in pregnant women with hypertension (Goodlin) (Letter); (Sowers and Zemel) (Reply). 1990;163:261-2
Intrapartum asphyxia; *see* **Fetal anoxia**
Intrauterine devices
Cardiovascular death among women under 40 years of age using low-estrogen oral contraceptives and intrauterine devices in Finland from 1975 to 1984 (Hirvonen and Idänpään-Heikkilä). 1990;163:281-4 (Supplement)
Contraception and ectopic pregnancy risk (Franks et al). 1990;163:1120-3
Laparoscopic ventrosuspensions (Yoong). 1990;163:1151-3
Ovarian pregnancy: a report of 20 cases in one institution (Raziel et al). 1990;163:1182-5
Intrauterine growth retardation. Fetal growth retardation; *see* **Fetal growth retardation**
Intrauterine synechiae; *see* **Adhesions**
Intrauterine transfusion; *see* **Blood transfusion, intrauterine**
Ionized calcium; *see* **Calcium**
Irrigation
Smoking and the antioxidant ascorbic acid: plasma, leukocyte, and cervicovaginal cell concentrations in normal healthy women (Basu et al). 1990;163:1948-52
Islands of Langerhans
Anencephalics as organ donors (Van Assche). 1990;163:599-600
Isoenzymes
Effects of ritodrine tocolysis on cardiac isozymes and electrocardiography (Hendricks and Katz) (Letter); (Hadi and Albazzaz) (Reply). 1990;163:699-701
Isradipine
Effects of magnesium and isradipine on contractile activation induced by the thromboxane A_2 analog U46619 in human uteroplacental arteries in term pregnancy (Skajaa et al). 1990;163:1323-33
Items
Items. 1990;163:272, 714, 1108, 1378, 1718, 2032

J

Jurisprudence
A chill wind blows: Webster, obstetrics, and the health of women (Chavkin and Rosenfield). 1990;163:450-2 (Clin. opinion)

K

Karyotype abnormalities; *see* **Chromosome abnormalities**
Karyotyping
Effect of maternal-fetal movement on concentration of cells obtained at genetic amniocentesis (Carlan et al). 1990;163:490-3
Second-trimester placental biopsy for rapid fetal karyotyping (Cameron et al). 1990;163:931-4
Ketoconazole
Ketoconazole treatment of Cushing's syndrome in pregnancy (Divers). 1990;163:1101 (Letter)
Ketosis, diabetic
Diabetic ketoacidosis and insulin resistance with subcutaneous terbutaline infusion: a case report (Tibaldi et al). 1990;163:509-10
Kidney failure, chronic
Chronic renal disease and pregnancy outcome (Cunningham et al). 1990;163:453-9

L

Labor
Changes in active and latent collagenase in human placenta around the time of parturition (Rajabi et al). 1990;163:499-503
A comparison of the effect of epidural, general, and no anesthesia on funic acid-base values by stage of labor and type of delivery (Shyken et al). 1990;163:802-7
The course of labor after endurance exercise during pregnancy (Clapp). 1990;163:1799-805
The intrauterine sound environment of the human fetus during labor (Benzaquen et al). 1990;163:484-90
Labor epidural analgesia and dystocia-related cesarean section (Downing and Knape). 1990;163:1096-7 (Letter)

The role of fetal membranes in regulating production, transport, and metabolism of prostaglandin E_2 during labor (McCoshen et al). 1990;163:1632-40

Labor, induced

Double-blind comparison of intravaginal prostaglandin E_2 gel and "chip" for preinduction cervical ripening (Smith et al). 1990;163:845-7

Induction of labor with mifepristone (RU 486) in intrauterine fetal death (Cabrol et al). 1990;163:540-2

Induction of labor with pulsatile oxytocin (Cummiskey and Dawood). 1990;163:1868-74

Labor, induced, animal

Effect of intravaginal application of prostaglandin E_2 gel on the mechanical properties of the ovine cervix uteri at term (Owiny and Fitzpatrick). 1990;163:657-60

Labor, premature

Amniotic fluid glucose concentration: a rapid and simple method for the detection of intraamniotic infection in preterm labor (Romero et al). 1990;163:968-74

Antenatal microbiologic and maternal risk factors associated with prematurity (McGregor et al). 1990;163:1465-73

Awaiting cervical change for the diagnosis of preterm labor does not compromise the efficacy of ritodrine tocolysis (Utter et al). 1990;163:882-6

A comparison of tocolysis with nifedipine or ritodrine: analysis of efficacy and maternal, fetal, and neonatal outcome (Ferguson et al). 1990;163:105-11

The effect of physical activity during pregnancy on preterm delivery and birth weight (Klebanoff et al). 1990;163:1450-6

Evaluation of a risk scoring system as a predictor of preterm birth in an indigent population (Owen et al). 1990;163:873-9

Infection and labor. VI. Prevalence, microbiology, and clinical significance of intraamniotic infection in twin gestations with preterm labor (Romero et al). 1990;163:757-61

Is indicated or spontaneous preterm delivery more advantageous for the fetus? (Owen et al). 1990;163:868-72

A new tocolytic agent: development of an oxytocin antagonist for inhibiting uterine contractions (Wilson et al). 1990;163:195-202

Prediction of risk for preterm delivery by ultrasonographic measurement of cervical length (Andersen et al). 1990;163:859-67

Preterm delivery: a risk factor for retained placenta (Romero et al). 1990;163:823-5

A prospective randomized comparison of oral terbutaline and magnesium oxide for the maintenance of tocolysis (Ridgway et al). 1990;163:879-82

Randomized investigation of magnesium sulfate for prevention of preterm birth (Cox et al). 1990;163:767-72

Risk factors for preterm premature rupture of fetal membranes: a multicenter case-control study (Harger et al). 1990;163:130-7

Secretion of phospholipases by bacterial pathogens may initiate preterm labor (Bennett et al). 1990;163:241-2 (Letter)

Labor, premature, animal

Inhibition of spontaneous uterine contractions during the last trimester in pregnant baboons by an oxytocin antagonist (Wilson et al). 1990;163:1875-82

A rabbit model for bacteria-induced preterm pregnancy loss (Dombroski et al). 1990;163:1938-43

Labor complications

Effect of uterine contractility and maternal hypotension on prolonged decelerations after bupivacaine epidural anesthesia (Steiger and Nageotte). 1990;163:808-12

Uterine hyperstimulation after low-dose prostaglandin E_2 therapy: tocolytic treatment in 181 cases (Egarter et al). 1990;163:794-6

Labor stage, third

Preterm delivery: a risk factor for retained placenta (Romero et al). 1990;163:823-5

Laboratory diagnosis; *see* **Diagnosis, laboratory**

Laparoscopy; *see* **Peritoneoscopy**

Laparotomy

Management of selected cystic adnexal masses in postmenopausal women by operative laparoscopy: a pilot study (Parker and Berek). 1990;163:1574-7

Larynx, abnormalities

Prenatal diagnosis of laryngeal atresia (Watson et al). 1990;163:1456-7

Laser surgery

Carbon dioxide laser energy disperses human papillomavirus deoxyribonucleic acid onto treatment fields (Ferenczy et al). 1990;163:1271-4

Fluid cooling of artificial sapphire tips of laser (Loffer) (Letter); (Baggish) (Reply). 1990;163:681

Sapphire probes in obstetric laser surgery (Corson) (Letter); (Baggish and Daniell) (Reply). 1990;163:246-7

Lectins

Lectins and heparin-binding features of human spermatozoa as analyzed by flow cytometry (Vasquez et al). 1990;163:2006-12

Leiomyoma

Collagen metabolism in gynecologic patients: changes in the concentration of the aminoterminal propeptide of type III procollagen in serum (Puistola et al). 1990;163:1276-81

Efficacy and safety considerations in women with uterine leiomyomas treated with gonadotropin-releasing hormone agonists: the estrogen threshold hypothesis (Friedman et al). 1990;163:1114-9 (Clin. opinion)

Malignant leiomyomatosis peritonealis disseminata (Akkersdijk et al). 1990;163:591-3

Preferential mitogenic activity for myoblast-like cells can be extracted from uterine leiomyoma tissues (Koutsilieris et al). 1990;163:1665-70

Leiomyomatosis; *see* **Leiomyoma**

Leiomyosarcoma

Malignant leiomyomatosis peritonealis disseminata (Akkersdijk et al). 1990;163:591-3

Letters

Letters. 1990;163:240-71, 677-712, 1089-107, 1364-77, 1713-7, 2024-30

Leukocytes

Lymphokine production during term human pregnancy: differences between peripheral leukocytes and decidual cells (Dudley et al). 1990;163:1890-3

Leuprolide

Effects of danazol, gonadotropin-releasing hormone agonist, and a combination of danazol and gonadotropin-releasing hormone agonist on experimental endometriosis (Sakata et al). 1990;163:1679-84

Levonorgestrel

Binding of oral contraceptive progestogens to serum proteins and cytoplasmic receptor (Juchem and Pollow). 1990;163:2171-83 (Symposium)

Levonorgestrel—cont'd
Effects of three combined oral contraceptive preparations containing desogestrel plus ethinyl estradiol on lipid metabolism in comparison with two levonorgestrel preparations (Kloosterboer and Rekers). 1990;163:370-3 (Supplement)
Metabolic changes during treatment with two different progestogens (Refn et al). 1990;163:374-7 (Supplement)
Pharmacokinetics of gestagens: some problems (Fotherby). 1990;163:323-8 (Supplement)
Pharmacokinetics of the contraceptive steroids levonorgestrel and gestodene after single and multiple oral administration to women (Kuhnz). 1990;163:2120-7 (Symposium)
LH
Antiprogestin treatment decreases midluteal luteinizing hormone pulse amplitude and primarily exerts a pituitary inhibition (Shoupe et al). 1990;163:1982-5
The GnRH pulse generator (Knobil). 1990;163:1721-6 (Supplement)
Gonadotropin-releasing hormone deficiency in men: diagnosis and treatment with exogenous gonadotropin-releasing hormone (Crowley and Whitcomb). 1990;163:1752-8 (Supplement)
The luteinizing hormone–releasing hormone pulse generator in men: abnormalities and clinical management (Matsumoto et al). 1990;163:1743-51 (Supplement)
Nature of gonadotropin-releasing hormone self-priming of luteinizing hormone secretion during the normal menstrual cycle (Sollenberger et al). 1990;163:1529-34
Ovulation prediction from cyclic changes in salivary electrical conductivity (Loewit et al). 1990;163:708-10 (Letter)
LH-FSH releasing hormone
The luteinizing hormone–releasing hormone pulse generator in men: abnormalities and clinical management (Matsumoto et al). 1990;163:1743-51 (Supplement)
Lichen sclerosis; *see* **Vulvar diseases**
Lidocaine
Effectiveness of 1% lidocaine dorsal penile nerve block in infant circumcision (Arnett et al). 1990;163:1074-80
Life tables
Survival rates of monoamniotic twins do not decrease after 30 weeks' gestation (Carr et al). 1990;163:719-22
Lipids
The clinical relevance of oral contraceptive pill–induced plasma lipid changes: facts and fiction (Hoppe). 1990;163:388-91 (Supplement)
Effect of low-dose oral contraceptives on carbohydrate and lipid metabolism in women with recent gestational diabetes: results of a controlled, randomized, prospective study (Kjos et al). 1990;163:1822-7
Effects of oral contraceptives on carbohydrate and lipid metabolisms in a healthy population: the Telecom Study (Simon et al). 1990;163:382-7 (Supplement)
Effects of oral contraceptives on lipid metabolism (Gevers Leuven et al). 1990;163:1410-3 (Supplement)
Effects of three combined oral contraceptive preparations containing desogestrel plus ethinyl estradiol on lipid metabolism in comparison with two levonorgestrel preparations (Kloosterboer and Rekers). 1990;163:370-3 (Supplement)
Evidence of heterogeneous mechanisms in lipoprotein lipid alterations in hyperandrogenic women (Wild et al). 1990;163:1998-2005
Interrelations between carbohydrates, lipids, and the hemostatic system in relation to the risk of thrombotic and cardiovascular disease (Juhan-Vague and Vague). 1990;163:313-5 (Supplement)
Mechanism of action of oral contraceptives on carbohydrate metabolism at the cellular level (Skouby et al). 1990;163:343-8 (Supplement)
Metabolic changes during the normal menstrual cycle: a longitudinal study (Lebech et al). 1990;163:414-6 (Supplement)
Metabolic changes during treatment with two different progestogens (Refn et al). 1990;163:374-7 (Supplement)
Oral contraceptives in risk groups: Exclusion or monitoring? (Guillebaud). 1990;163:443-6 (Supplement)
Some aspects of the relationship between oral contraceptives, lipid abnormalities, and cardiovascular disease (Samsioe and Mattsson). 1990;163:354-8 (Supplement)
Time-dependent alterations in lipid metabolism during treatment with low-dose oral contraceptives (Kuhl et al). 1990;163:363-9 (Supplement)
Lipogenesis; *see* **Lipids**
Lipoproteins
The clinical relevance of oral contraceptive pill–induced plasma lipid changes: facts and fiction (Hoppe). 1990;163:388-91 (Supplement)
Estrogenic effect of gestodene- or desogestrel-containing oral contraceptives on lipoprotein metabolism (Gevers Leuven et al). 1990;163:358-62 (Supplement)
Oral contraceptives, lipoproteins, and atherosclerosis (Adams et al). 1990;163:1388-92 (Supplement)
Role of plasma lipoproteins in the pathogenesis of atherosclerotic disease, with special reference to sex hormone effects (Tikkanen). 1990;163:296-304 (Supplement)
Some aspects of the relationship between oral contraceptives, lipid abnormalities, and cardiovascular disease (Samsioe and Mattsson). 1990;163:354-8 (Supplement)
Time-dependent alterations in lipid metabolism during treatment with low-dose oral contraceptives (Kuhl et al). 1990;163:363-9 (Supplement)
Lipoproteins, HDL
Evidence of heterogeneous mechanisms in lipoprotein lipid alterations in hyperandrogenic women (Wild et al). 1990;163:1998-2005
Lipoproteins, HDL cholesterol
The clinical relevance of oral contraceptive pill–induced plasma lipid changes: facts and fiction (Hoppe). 1990;163:388-91 (Supplement)
Lipoproteins, LDL cholesterol
The clinical relevance of oral contraceptive pill–induced plasma lipid changes: facts and fiction (Hoppe). 1990;163:388-91 (Supplement)
Listeria
Intrauterine *Listeria* infection: prenatal diagnosis by biophysical assessment and amniocentesis (Liner). 1990;163:1596-7
Liver
Liver histopathologic findings in women with sickle cell disease given prophylactic transfusion during pregnancy (Yeomans et al). 1990;163:958-64
Long-term maternal-fetal exposure to high-low insulin concentrations alter liver but not brain insulin receptors (Devaskar et al). 1990;163:1350-6
Studies on the mechanism of action of oral contraceptives with regard to fibrinolytic variables (Kooistra et al). 1990;163:404-13 (Supplement)
Liver diseases
Endometrioma of the liver (Rovati et al). 1990;163:1490-2

Oral contraception in disease states (Breckwoldt et al). 1990;163:2213-6 (Symposium)
Recurrent acute fatty liver of pregnancy (Barton et al). 1990;163:534-8
Longitudinal studies
Longitudinal study of the renin-angiotensin-aldosterone system in hypertensive pregnant women: deviations related to the development of superimposed preeclampsia (August et al). 1990;163:1612-21
Metabolic changes during the normal menstrual cycle: a longitudinal study (Lebech et al). 1990;163:414-6 (Supplement)
Low birth weight infant; *see* **Infant, low birth weight**
Lung
Ductus arteriosus flow velocity modulation by fetal breathing movements as a measure of fetal lung development (van Eyck et al). 1990;163:558-66
Lung, animal
Dose response of thyrotropin-releasing hormone on pulmonary maturation in corticosteroid-treated preterm rabbits (Tabor et al). 1990;163:669-76
Effects of clonidine on breathing movements and electrocortical activity in the fetal lamb (Bamford et al). 1990;163:661-8
Lupus anticoagulant
Laboratory identification of the lupus anticoagulant in normal pregnancy and pregnancy-induced hypertension (Riveros et al) (Letter); (Lockwood) (Reply). 1990;163:704-5
Luteal phase
Luteal insufficiency: correlation between endometrial dating and integrated progesterone output in clomiphene citrate–induced cycles (Hecht et al). 1990; 163:1986-91
Luteinizing hormone; *see* **LH**
Lutrepulse; *see* **Pituitary hormone releasing hormones, analogs and derivatives**
Lymph nodes
The use of in situ hybridization to show human papillomavirus deoxyribonucleic acid in metastatic cancer cells within lymph nodes (Lewandowski et al). 1990;163:1333-7
Lymphangioma
Spontaneous resolution of a nuchal fetal cystic hygroma diagnosed early in the second trimester of pregnancy (Meizner et al) (Letter); (Bronshstein and Blumenfeld) (Reply). 1990;163:267-9
Lymphocyte stimulation; *see* **Lymphocyte transformation**
Lymphocyte transformation
Lymphocyte proliferative response to fertilization antigen in patients with antisperm antibodies (Naz et al). 1990;163:610-3
Lymphokines
Lymphokine production during term human pregnancy: differences between peripheral leukocytes and decidual cells (Dudley et al). 1990;163:1890-3

M

Macaca fascicularis
Effects on bone of surgical menopause and estrogen therapy with or without progesterone replacement in cynomolgus monkeys (Jayo et al). 1990;163:614-8
Macaca mulatta
Alteration of 24-hour rhythms in myometrial activity in the chronically catheterized pregnant rhesus monkey after a 6-hour shift in the light-dark cycle (Figueroa et al). 1990;163:648-54
Macrosomia
Infants of diabetic mothers with accelerated fetal growth by ultrasonography: Are they all alike? (Keller et al). 1990;163:893-7
Magnesium
Effect of tocolytic agents on fetal umbilical velocimetry (Wright et al). 1990;163:748-50
Effects of magnesium and isradipine on contractile activation induced by the thromboxane A_2 analog U46619 in human uteroplacental arteries in term pregnancy (Skajaa et al). 1990;163:1323-33
Magnesium supplementation in pregnancy (Spätling and Fallenstein) (Letter); (Sibai) (Reply). 1990;163:240-1
Magnesium oxide
A prospective randomized comparison of oral terbutaline and magnesium oxide for the maintenance of tocolysis (Ridgway et al). 1990;163:879-82
Magnesium sulfate
Adjusting the loading dose of magnesium sulfate for tocolysis (Wright et al). 1990;163:889-92
Combination therapy has potential complications (Frohlich) (Letter); (Snyder and Cardwell) (Reply). 1990;163: 244
Magnesium sulfate and promethazine do not interact to cause hypotension in gravid ewes (Pollack et al). 1990;163:787-94
Magnesium sulfate is not an ideal anticonvulsant (Goodlin) (Letter); (Sibai) (Reply). 1990;163:1714-5
Neuroophthalmologic effects of intravenous magnesium sulfate (Digre et al). 1990;163:1848-52
Nifedipine enhances the cardiac toxicity of magnesium sulfate in the isolated perfused Sprague-Dawley rat heart (Thorp et al). 1990;163:655-6
Phenytoin and magnesium sulfate in eclampsia (Dommisse) (Letter); (Ryan) (Reply). 1990;163:1089-91
Randomized investigation of magnesium sulfate for prevention of preterm birth (Cox et al). 1990;163: 767-72
Magnetic resonance imaging
Pelvimetry by magnetic resonance imaging in breech presentation (van Loon et al). 1990;163:1256-60
Prenatal diagnosis of fetal intracranial calcifications (Koga et al). 1990;163:1543-5
Study of internal structure of the human fetus in utero by echo-planar magnetic resonance imaging (Johnson et al). 1990;163:601-7
Major histocompatibility complex
Sharing of human leukocyte antigens in primary and secondary recurrent spontaneous abortions (Ho et al). 1990;163:178-88
Mammography
Breast disease programs and mammography training (Dodd and McLelland) (Letter); (Gleicher) (Reply). 1990;163:689-91
Martin-Bell syndrome
Cytogenetic uncertainties surrounding the fragile X in Martin-Bell syndrome (Sindwani and Verma). 1990;163:1713-4 (Letter)
Marvelon; *see* **Desogestrel/ethinyl estradiol**
Masculinization; *see* **Sex characteristics**
Mass screening
Intrapartum hepatitis B screening in a low-risk population (Ernest et al). 1990;163:978-80
The perinatal impact of cocaine, amphetamine, and opiate

Mass screening—cont'd
use detected by universal intrapartum screening (Gillogley et al). 1990;163:1535-42
Maternal alcohol abuse; *see* **Alcoholism**
Maternal-fetal exchange
The effect of maternal hyperoxia on behavioral activity in growth-retarded human fetuses (Gagnon et al). 1990;163:1894-9
Metabolism of cocaine by human placentas: implications for fetal exposure (Roe et al). 1990;163:715-8
Placental transfer of cefazolin and piperacillin in pregnancies remote from term complicated by Rh isoimmunization (Brown et al). 1990;163:938-43
Maternal-fetal exchange, animal
Transplacental transfer of zidovudine in the near-term pregnant baboon (Hankins et al). 1990;163:728-32
Maternal metabolism; *see* **Metabolism**
Maternal mortality
Can anesthetic-related maternal mortality be reduced? (Conklin). 1990;163:253-4 (Letter)
A chill wind blows: Webster, obstetrics, and the health of women (Chavkin and Rosenfield). 1990;163:450-2 (Clin. opinion)
Cocaine-related maternal death (Burkett et al). 1990;163:40-1
Maternal outcome; *see* **Pregnancy outcome**
Maternal serum α-fetoproteins; *see* **Alpha fetoproteins**
Matrix glycoprotein receptors; *see* **Receptors, glycoprotein**
Maylard incision
The Maylard incision in gynecologic cancer (Helmkamp and Krebs). 1990;163:1554-7
Mean arterial blood pressure; *see* **Blood pressure**
Meconium aspiration
Amnioinfusion and prevention of meconium aspiration syndrome (Falciglia) (Letter); (Sadovsky and Amon) (Reply). 1990;163:258-9
Is meconium aspiration an intrauterine event? (Falciglia) (Letter); (Kalhan et al) (Reply). 1990;163:250-1
Medical education; *see* **Education, medical**
Medical ethics; *see* **Ethics**
Medical residency; *see* **Internship and residency**
Medroxyprogesterone
Comparison of norethindrone and medroxyprogesterone acetate with natural progesterone and estradiol in stimulating prolactin production from cultured endometrial stromal cells (Levin et al). 1990;163:1932-8
Membrane glycoproteins
Epithelial cells from normal human endometrium express a tumor-associated glycoprotein (TAG-72) epitope in vitro (Osteen et al). 1990;163:479-84
Meningomyelocele
Diagnosis and management of prenatally detected myelomeningocele: a preliminary report (Hogge et al). 1990;163:1061-5
Menopause
Endometrial assessment by vaginal ultrasonography before endometrial sampling in patients with postmenopausal bleeding (Goldstein et al). 1990;163:119-23
Management of selected cystic adnexal masses in postmenopausal women by operative laparoscopy: a pilot study (Parker and Berek). 1990;163:1574-7
Relationship between plasma calcium fractions, other bone-related variables, and serum follicle-stimulating hormone levels in premenopausal, perimenopausal, and postmenopausal women (Nordin et al). 1990;163:140-5
Short-term effects of smoking on the pharmacokinetic profiles of micronized estradiol in postmenopausal women (Cassidenti et al). 1990;163:1953-60
Menopause, premature, animal
Effects on bone of surgical menopause and estrogen therapy with or without progesterone replacement in cynomolgus monkeys (Jayo et al). 1990;163:614-8
Menorrhagia
Early hypothyroidism in patients with menorrhagia (Blesing and Hambley) (Letter); (Wilansky and Greisman) (Reply). 1990;163:697
Screening infertile women for subclinical hypothyroidism (Strickland et al) (Letter); (Wilansky and Greisman) (Reply). 1990;163:262-3
Menstrual cycle
Changes in platelet angiotensin II binding sites associated with the human menstrual cycle (Baker et al). 1990;163:175-6
Luteal insufficiency: correlation between endometrial dating and integrated progesterone output in clomiphene citrate–induced cycles (Hecht et al). 1990;163:1986-91
Metabolic changes during the normal menstrual cycle: a longitudinal study (Lebech et al). 1990;163:414-6 (Supplement)
Nature of gonadotropin-releasing hormone self-priming of luteinizing hormone secretion during the normal menstrual cycle (Sollenberger et al). 1990;163:1529-34
Mental retardation
Prognosis for twins with birth weight <1500 gm: the impact of cesarean section in relation to fetal presentation (Rydhström). 1990;163:528-33
Mesenteric arteries, animal
Role of the endothelium in adrenergic responses of mesenteric artery rings of pregnant rats (Parent et al). 1990;163:229-34
Mestranol
Pharmacokinetics of ethinyl estradiol and mestranol (Goldzieher and Brody). 1990;163:2114-9 (Symposium)
Metabolic diseases, complications
Interrelations between carbohydrates, lipids, and the hemostatic system in relation to the risk of thrombotic and cardiovascular disease (Juhan-Vague and Vague). 1990;163:313-5 (Supplement)
Metabolism
Correlations between antepartum maternal metabolism and newborn behavior (Rizzo et al). 1990;163:1458-64
Metalloproteinases, antagonists or inhibitors
Changes in active and latent collagenase in human placenta around the time of parturition (Rajabi et al). 1990;163:499-503
Metastasis; *see* **Neoplasm metastasis**
Methotrexate
Treatment of cervical pregnancy with methotrexate (Sherer) (Letter); (Palti) (Reply). 1990;163:693-4
Methoxyverapamil; *see* **Verapamil**
Mice
Ovarian granulosa cell tumorigenesis in SWR-derived F1 hybrid mice: preneoplastic follicular abnormality and malignant disease progression (Tennent et al). 1990;163:625-34
Microspheres
Venous and hepatic vascular responses to indomethacin and prostaglandin E_1 in the fetal lamb (Paulick et al). 1990;163:1357-63
Microsurgery
Adhesion formation after ovarian wound repair in New

Zealand white rabbits: a comparison of ovarian microsurgical closure with ovarian nonclosure (Wiskind et al). 1990;163:1674-8

Mifepristone
Antiprogestin treatment decreases midluteal luteinizing hormone pulse amplitude and primarily exerts a pituitary inhibition (Shoupe et al). 1990;163:1982-5
In vitro effect of RU 486 on sperm-egg interaction in mice (Juneja and Dodson). 1990;163:216-21
Induction of labor with mifepristone (RU 486) in intrauterine fetal death (Cabrol et al). 1990;163:540-2
Mifepristone (RU 486) failure in an ovarian heterotopic pregnancy (Levin et al). 1990;163:543-4

Migraine
Oral contraceptives in risk groups: Exclusion or monitoring? (Guillebaud). 1990;163:443-6 (Supplement)

Milk, human
Distribution of CA 125 in embryonic tissues and adult derivatives of the fetal periderm (Hardardottir et al). 1990;163:1925-31

Mitochondria
Ultrastructural aspects of preeclampsia. II. Mitochondrial changes (Shanklin and Sibai). 1990;163:943-53

Mitogens, endogenous; *see* **Growth substances**

Mitral valve, surgery
Effect of mitral valve prosthetic surgery on the outcome of a growth-retarded fetus: a case report (Izquierdo et al). 1990;163:584-7

Mitral valve stenosis
β-Adrenergic receptor blockade in the management of pregnant women with mitral stenosis (Al Kasab et al). 1990;163:37-40

Mole, hydatidiform; *see* **Hydatidiform mole**

Molybdenum, deficiency
Antenatal diagnosis of molybdenum cofactor deficiency (George et al). 1990;163:1203-4

Moniliasis, vulvovaginal
Bacterial vaginosis and trichomoniasis vaginitis are risk factors for cuff cellulitis after abdominal hysterectomy (Soper et al). 1990;163:1016-23

Monkeys, cynomolgus; *see* ***Macaca fascicularis***

Monkeys, rhesus; *see* ***Macaca mulatta***

Monoamniotic twins; *see* **Twins, monozygotic**

Monoclonal antibodies; *see* **Antibodies, monoclonal**

Morbidity
The differential neonatal morbidity of the intrauterine growth retardation syndrome (Villar et al). 1990;163:151-7
Epidemiology of preeclampsia and eclampsia in the United States, 1979-1986 (Saftlas et al). 1990;163:460-5
Perinatal survival with expectant management of midtrimester rupture of membranes (Major and Kitzmiller). 1990;163:838-44

Mortality; *see* **Infant mortality**; **Maternal mortality**

Multiple drug resistance; *see* **Drug resistance**

Multiple endocrine adenomatosis; *see* **Neoplasms, multiple endocrine**

Multiple pregnancy; *see* **Pregnancy, multiple**

Muscle, smooth
Gestational changes in mechanical properties of skinned muscle tissues of human myometrium (Izumi et al). 1990;163:638-47

Mycoplasma infections
Cervicovaginal microflora and pregnancy outcome: results of a double-blind, placebo-controlled trial of erythromycin treatment (McGregor et al). 1990;163:1580-91

Myelomeningocele; *see* **Meningomyelocele**

Myoblastoma
Preferential mitogenic activity for myoblast-like cells can be extracted from uterine leiomyoma tissues (Koutsilieris et al). 1990;163:1665-70

Myocardial infarction
Oral contraceptives and myocardial infarction (Thorneycroft). 1990;163:1393-7 (Supplement)
Past use of oral contraceptives and cardiovascular disease: a meta-analysis in the context of the Nurses' Health Study (Stampfer et al). 1990;163:285-91 (Supplement)

Myoma
Studies of the spontaneous motility and the effect of histamine on isolated myometrial strips of the nonpregnant human uterus: the influence of various uterine abnormalities (Martinez-Mir et al). 1990;163:189-95

Myometrium
Gestational changes in mechanical properties of skinned muscle tissues of human myometrium (Izumi et al). 1990;163:638-47
Studies of the spontaneous motility and the effect of histamine on isolated myometrial strips of the nonpregnant human uterus: the influence of various uterine abnormalities (Martinez-Mir et al). 1990;163:189-95

Myometrium, animal
Alteration of 24-hour rhythms in myometrial activity in the chronically catheterized pregnant rhesus monkey after a 6-hour shift in the light-dark cycle (Figueroa et al). 1990;163:648-54

N

Naloxone
Neuromodulatory regulation of gonadotropin-releasing hormone pulsatile discharge in women (Jaffe et al). 1990;163:1727-31 (Supplement)

Narcotics; *see also specific drugs*
The perinatal impact of cocaine, amphetamine, and opiate use detected by universal intrapartum screening (Gillogley et al). 1990;163:1535-42

Natriuretic peptides, atrial
Interrelationship between atrial natriuretic factor concentrations and acute volume expansion in pregnant and nonpregnant women (Hatjis et al). 1990;163:45-50
Plasma atrial arginine vasopressin levels vary little between preeclamptic and control patients (Elias and Varizi). 1990;163:245 (Letter)

Necrotizing fasciitis; *see* **Fasciitis**

Negroid race
The effect of race on the relationship between fetal death and altered fetal growth (Ferguson and Myers). 1990;163:1222-30

Neonatal intensive care; *see* **Intensive care, neonatal**

Neonatal mortality; *see* **Infant mortality**

Neonatal outcome; *see* **Pregnancy outcome**

Neonatal screening
Cost-effectiveness of intrapartum screening and treatment for maternal group B streptococci colonization (Strickland et al). 1990;163:4-8 (Clin. opinion)

Neonatal sepsis; *see* **Infant, newborn, diseases**

Neoplasm invasiveness
Invasive carcinoma of the vulva (Cavanagh et al). 1990;163:1007-15

Neoplasm metastasis
The use of in situ hybridization to show human papillomavirus deoxyribonucleic acid in metastatic cancer cells within lymph nodes (Lewandowski et al). 1990;163:1333-7
Neoplasms, multiple endocrine
Multiple endocrine adenomatosis type I in pregnancy (Smythe et al). 1990;163:1037-9
Nephrogenic diabetes insipidus; *see* **Diabetes insipidus**
Nerve block
Effectiveness of 1% lidocaine dorsal penile nerve block in infant circumcision (Arnett et al). 1990;163:1074-80
Neuromuscular blocking agents
Differential sensitivities of fetal muscle groups to *d*-tubocurarine (Szeto and Hinman). 1990;163:202-9
Neuroophthalmologic effects; *see* **Eye, physiopathology**
Newborn diseases; *see* **Infant, newborn, diseases**
Niemann-Pick disease
Niemann-Pick disease associated with nonimmune hydrops fetalis (Meizner et al). 1990;163:128-9
Nifedipine
Combination therapy has potential complications (Frohlich) (Letter); (Snyder and Cardwell) (Reply). 1990;163:244
A comparison of tocolysis with nifedipine or ritodrine: analysis of efficacy and maternal, fetal, and neonatal outcome (Ferguson et al). 1990;163:105-11
The effect of nifedipine therapy on fetal and placental Doppler waveforms in preeclampsia remote from term (Moretti et al). 1990;163:1844-8
Nifedipine enhances the cardiac toxicity of magnesium sulfate in the isolated perfused Sprague-Dawley rat heart (Thorp et al). 1990;163:655-6
Vasodilatory effects of nifedipine, methoxyverapamil, and sodium nitroprusside on contractile responses of the ewe uterine artery at term pregnancy (Isla and Dyer). 1990;163:1337-44
Nitroprusside
The effect of adrenocorticotropic hormone infusion on subsequent pituitary response in the sheep fetus (Cuthrell et al). 1990;163:170-4
Vasodilatory effects of nifedipine, methoxyverapamil, and sodium nitroprusside on contractile responses of the ewe uterine artery at term pregnancy (Isla and Dyer). 1990;163:1337-44
Nonimmune hydrops; *see* **Edema**
Nonstress tests; *see* **Fetal monitoring**
Nonsuppressible insulin-like activity
Insulin-like growth factor II and nonsuppressible insulin-like activity levels in newborns (Samaan et al). 1990;163:1836-9
Norepinephrine
Progesterone increases cardiovascular toxicity to cocaine in nonpregnant ewes (Plessinger and Woods). 1990;163:1659-64
Norethindrone
Comparison of norethindrone and medroxyprogesterone acetate with natural progesterone and estradiol in stimulating prolactin production from cultured endometrial stromal cells (Levin et al). 1990;163:1932-8
Norgestimate
Binding of oral contraceptive progestogens to serum proteins and cytoplasmic receptor (Juchem and Pollow). 1990;163:2171-83 (Symposium)
Gastrointestinal metabolism of contraceptive steroids (Back et al). 1990;163:2138-45 (Symposium)
Pharmacologic and pharmacokinetic characteristics of norgestimate and its metabolites (McGuire et al). 1990;163:2127-31 (Symposium)
Nuchal cystic hygroma; *see* **Lymphangioma**
Nucleotide mapping
Differential diagnosis between complete mole and hydropic abortus by deoxyribonucleic acid fingerprints (Nobunaga et al). 1990;163:634-8
Discrepancy in the diagnoses of hydatidiform mole by macroscopic and microscopic findings and the deoxyribonucleic acid fingerprint method (Takahashi et al). 1990;163:112-3

O

Obesity in diabetes
Does fasting interval affect the glucose challenge test? (Berkus et al). 1990;163:1812-7
Obstetrical forceps
Risk factors for third-degree and fourth-degree perineal lacerations in forceps and vacuum deliveries (Combs et al). 1990;163:100-4
Use of midforceps applauded (Escamilla). 1990;163:2027 (Letter)
Obstetrics
A chill wind blows: Webster, obstetrics, and the health of women (Chavkin and Rosenfield). 1990;163:450-2 (Clin. opinion)
Oligohydramnios; *see* **Amniotic fluid**
Omphalocele; *see* **Hernia, umbilical**
Oocytes
Factors affecting embryo implantation after human in vitro fertilization: a hypothesis (Paulson et al). 1990;163:2020-3
Human oocyte and preembryo donation: an evolving method for the treatment of infertility (Sauer and Paulson). 1990;163:1421-4 (Clin. opinion)
Oocytes, animal
Platelet activating factor enhances in vitro fertilization of rabbit oocytes (Roudebush et al). 1990;163:1670-3
Oophorectomy; *see* **Ovariectomy**
Oophoritis
Collagen metabolism in gynecologic patients: changes in the concentration of the aminoterminal propeptide of type III procollagen in serum (Puistola et al). 1990;163:1276-81
Operative laparoscopy; *see* **Laparotomy**
Opiates; *see* **Narcotics**
Opioid peptides; *see* **Endorphins**
Organ donors; *see* **Tissue donors**
Orthostatic hypotension; *see* **Hypotension, orthostatic**
Osteomyelitis
Postpartum osteomyelitis caused by group B streptococcus (Berkowitz and McCaffrey). 1990;163:1200-1
Osteoporosis
Prevalence and determinants of estrogen replacement therapy in elderly women (Cauley et al). 1990;163:1438-44
The relationship between plasma estradiol and the increase in bone density in postmenopausal women after treatment with subcutaneous hormone implants (Studd et al). 1990;163:1474-9
Osteoporosis, animal
Effects on bone of surgical menopause and estrogen therapy with or without progesterone replacement in cynomolgus monkeys (Jayo et al). 1990;163:614-8

Outpatients
Outpatient obstetric management of women with type I diabetes (Bourgeois and Duffer). 1990;163:1065-73
Ovarian cysts
Hemoperitoneum as a result of coital injury without associated vaginal injury (McColgin et al). 1990;163:1503-5
Ovarian diseases
Specific binding sites for insulin-like growth factor I in the ovarian stroma of women with polycystic ovarian disease and stromal hyperthecosis (Nagamani and Stuart). 1990;163:1992-7
Ovarian failure; *see* **Ovary, physiopathology**
Ovarian neoplasms
Autologous antibodies eluted from membrane fragments in human ovarian epithelial neoplastic effusions. III. Cytotoxic potential in vitro and characterization of antigen(s) (Kutteh et al). 1990;163:1301-6
Collagen metabolism in gynecologic patients: changes in the concentration of the aminoterminal propeptide of type III procollagen in serum (Puistola et al). 1990;163:1276-81
Expression of P-glycoprotein in epithelial ovarian cancer: evaluation as a marker of multidrug resistance (Rubin et al). 1990;163:69-73
The prognostic significance of CA 125 half-life in patients with ovarian cancer who have received primary chemotherapy after surgical cytoreduction (Hunter et al). 1990;163:1164-7
Proliferative and antiproliferative effects of interferon-γ and tumor necrosis factor-α on cell lines derived from cervical and ovarian malignancies (Mutch et al). 1990;163:1920-4
Ovarian pregnancy; *see* **Pregnancy, ectopic**
Ovarian stroma, pathology; *see* **Stroma ovarii, pathology**
Ovariectomy
Parameters of hypothalamic aging (Seifer and Jones) (Letter); (Alexander and Aksel) (Reply). 1990;163:1715
Ovariectomy, animal
Effects on bone of surgical menopause and estrogen therapy with or without progesterone replacement in cynomolgus monkeys (Jayo et al). 1990;163:614-8
Ovary, physiology
Oxytocin and vasopressin binding sites in human and bovine ovaries (Fuchs et al). 1990;163:1961-7
Ovary, physiology, animal
Oxytocin and vasopressin binding sites in human and bovine ovaries (Fuchs et al). 1990;163:1961-7
Ovary, physiopathology
Human oocyte and preembryo donation: an evolving method for the treatment of infertility (Sauer and Paulson). 1990;163:1421-4 (Clin. opinion)
Ovary, surgery, animal
Adhesion formation after ovarian wound repair in New Zealand white rabbits: a comparison of ovarian microsurgical closure with ovarian nonclosure (Wiskind et al). 1990;163:1674-8
Oviducts, mammalian; *see* **Fallopian tubes**
Ovulation
Inhibition of ovulation by low-dose monophasic contraceptive containing gestodene (Thomas and Vankrieken). 1990;163:1404-9 (Supplement)
Ovulation detection
Ovulation prediction from cyclic changes in salivary electrical conductivity (Loewit et al). 1990;163:708-10 (Letter)
Ovulation induction
Polycystic ovary syndrome: abnormalities and management with pulsatile gonadotropin-releasing hormone and gonadotropin-releasing hormone analogs (Filicori et al). 1990;163:1737-42 (Supplement)
Ovum implantation
Factors affecting embryo implantation after human in vitro fertilization: a hypothesis (Paulson et al). 1990;163:2020-3
Tubal embryo successfully transferred in utero (Shettles). 1990;163:2026-7 (Letter)
Ovum transport
The complex nature of egg transport through the oviduct (Egarter) (Letter); (Pulkkinen and Jaakkola) (Reply). 1990;163:687-8
Oxytocin
Induction of labor with pulsatile oxytocin (Cummiskey and Dawood). 1990;163:1868-74
Oxytocin and vasopressin binding sites in human and bovine ovaries (Fuchs et al). 1990;163:1961-7
Oxytocin, antagonists and inhibitors
Inhibition of spontaneous uterine contractions during the last trimester in pregnant baboons by an oxytocin antagonist (Wilson et al). 1990;163:1875-82
A new tocolytic agent: development of an oxytocin antagonist for inhibiting uterine contractions (Wilson et al). 1990;163:195-202

P

P-glycoprotein; *see* **Glycoproteins**
Packed red blood cells; *see* **Blood transfusion**
Pain
Laparoscopic ventrosuspensions (Yoong). 1990;163:1151-3
Pancreas transplantation
Anencephalics as organ donors (Van Assche). 1990;163:599-600
Pancuronium
Differential sensitivities of fetal muscle groups to *d*-tubocurarine (Szeto and Hinman). 1990;163:202-9
Papanicolaou test; *see* **Uterus**
Papillary cystadenocarcinoma; *see* **Cystadenoma**
Papillomaviruses
Carbon dioxide laser energy disperses human papillomavirus deoxyribonucleic acid onto treatment fields (Ferenczy et al). 1990;163:1271-4
5-Fluorouracil exposure during the period of conception: report on two cases (Odom et al). 1990;163:76-7
The use of in situ hybridization to show human papillomavirus deoxyribonucleic acid in metastatic cancer cells within lymph nodes (Lewandowski et al). 1990;163:1333-7
Parity
Definition of primparas (Gates). 1990;163:677 (Letter)
Partial thromboplastin time
Antiphospholipid antibodies and recurrent pregnancy loss: correlation between the activated partial thromboplastin time and antibodies against phosphatidylserine and cardiolipin (Rote et al). 1990;163:575-84
Influence of oral contraceptives on coagulation tests in native blood and plasma (Kunz et al). 1990;163:417-20 (Supplement)
Parturition; *see* **Labor**
Parvovirus infections
Management and outcomes of pregnancies complicated by

Parvovirus infections—cont'd
human B19 parvovirus infection: a prospective study (Rodis et al). 1990;163:1168-71
Pelvic infection; *see* **Adnexitis**
Pelvic inflammatory disease; *see* **Adnexitis**
Pelvic tuberculosis; *see* **Tuberculosis, female genital**
Pelvimetry
Pelvimetry by magnetic resonance imaging in breech presentation (van Loon et al). 1990;163:1256-60
Vaginal breech delivery: a five-year prospective evaluation of a protocol using computed tomographic pelvimetry (Christian et al). 1990;163:848-55
Pemphigus
Pemphigus in pregnancy (Metzker and Merlob) (Letter); (Kanwar and Kaur) (Reply). 1990;163:1097
Penicillamine, adverse effects
Pregnancy in a patient with treated Wilson's disease: a case report (Dupont et al). 1990;163:1527-8
Penile nerve block; *see* **Nerve block**
Pentamidine
Drug prophylaxis for human immunodeficiency virus–infected pregnant women: ethical considerations (Minkoff and Moreno). 1990;163:1111-4 (Clin. opinion)
Embryofetal effects of pentamidine isethionate administered to pregnant Sprague-Dawley rats (Harstad et al). 1990;163:912-6
Pereyra procedure; *see* **Suspensions**
Periderm; *see* **Fetal development**
Perinatal mortality; *see* **Infant mortality**
Perinatal outcome; *see* **Pregnancy outcome**
Perineum, injuries
Risk factors for third-degree and fourth-degree perineal lacerations in forceps and vacuum deliveries (Combs et al). 1990;163:100-4
Peritoneoscopy
Laparoscopic diagnosis and treatment of interstitial ectopic pregnancy: a case report (Pasic and Wolfe). 1990;163:587-8
Laparoscopic ventrosuspensions (Yoong). 1990;163:1151-3
Mifepristone (RU 486) failure in an ovarian heterotopic pregnancy (Levin et al). 1990;163:543-4
Modified laparoscopy for monitoring transcervical surgery (Lin and Iwata). 1990;163:243-4 (Letter)
Peritoneum
Malignant leiomyomatosis peritonealis disseminata (Akkersdijk et al). 1990;163:591-3
Pessaries
A vesicovaginal fistula and intravesical foreign body: a rare case of the neglected pessary (Goldstein et al). 1990;163:589-91
pH; *see* **Hydrogen-ion concentration**
Pharmacokinetics
Influence of oral contraceptives on drug therapy (Teichmann). 1990;163:2208-13 (Symposium)
Interactions with oral contraceptives (Fotherby). 1990;163:2153-9 (Symposium)
Pharmacokinetics and pharmacodynamics of oral contraceptive steroids: factors influencing steroid metabolism (Jung-Hoffmann and Kuhl). 1990;163:2183-97 (Symposium)
Pharmacokinetics of ethinyl estradiol and mestranol (Goldzieher and Brody). 1990;163:2114-9 (Symposium)
Pharmacokinetics of gestagens: some problems (Fotherby). 1990;163:323-8 (Supplement)
Pharmacokinetics of gestodene and ethinyl estradiol after oral administration of a monophasic contraceptive (Täuber et al). 1990;163:1414-20 (Supplement)
Pharmacokinetics of the contraceptive steroids levonorgestrel and gestodene after single and multiple oral administration to women (Kuhnz). 1990;163:2120-7 (Symposium)
Pharmacologic and pharmacokinetic characteristics of norgestimate and its metabolites (McGuire et al). 1990;163:2127-31 (Symposium)
Protein binding of active ingredients and comparison of serum ethinyl estradiol sex hormone–binding globulin, corticosteroid-binding globulin, and cortisol levels in women using a combination of gestodene/ethinyl estradiol (Femovan) or a combination of desogestrel/ethinyl estradiol (Marvelon) and single-dose ethinyl estradiol bioequivalence from both oral contraceptives (Hümpel et al). 1990;163:329-33 (Supplement)
Selected aspects of the pharmacokinetics and metabolism of ethinyl estrogens and their clinical implications (Goldzieher). 1990;163:318-22 (Supplement)
Serum pharmacokinetics of orally administered desogestrel and binding of contraceptive progestogens to sex hormone–binding globulin (Bergink et al). 1990;163:2132-7 (Symposium)
Short-term effects of smoking on the pharmacokinetic profiles of micronized estradiol in postmenopausal women (Cassidenti et al). 1990;163:1953-60
Why do we need pharmacokinetic studies? (Hvidberg). 1990;163:316-8 (Supplement)
Phenotype
Correlation of the testicular determinant factor sequence zinc finger Y with varying gonadal phenotypes in a series of 13 subjects with gonadal dysgenesis because of Y aneuploidy (Tho et al). 1990;163:1968-75
Phenytoin
Phenytoin and magnesium sulfate in eclampsia (Dommisse) (Letter); (Ryan) (Reply). 1990;163:1089-91
Phosphatidylglycerols
Absence of evidence of pulmonary maturity at amniocentesis in term infants of diabetic mothers (Ojomo and Coustan). 1990;163:954-7
Phosphatidylserines
Antiphospholipid antibodies and recurrent pregnancy loss: correlation between the activated partial thromboplastin time and antibodies against phosphatidylserine and cardiolipin (Rote et al). 1990;163:575-84
Phospholipids
Antiphospholipid antibodies and recurrent pregnancy loss: correlation between the activated partial thromboplastin time and antibodies against phosphatidylserine and cardiolipin (Rote et al). 1990;163:575-84
Immunoglobulin G fractions from patients with antiphospholipid antibodies cause fetal death in BALB/c mice: a model for autoimmune fetal loss (Branch et al). 1990;163:210-6
Inhibitory cofactor of antiphospholipid antibody in normal pregnancy sera (Cheng). 1990;163:701 (Letter)
Recurrent adverse pregnancy outcome and antiphospholipid antibodies (Reece et al). 1990;163:162-9 (Curr. dev.)
Secretion of phospholipases by bacterial pathogens may initiate preterm labor (Bennett et al). 1990;163:241-2 (Letter)
Piperacillin
Placental transfer of cefazolin and piperacillin in pregnancies remote from term complicated by Rh isoimmunization (Brown et al). 1990;163:938-43

Pituitary-adrenal system, animal
The effect of adrenocorticotropic hormone infusion on subsequent pituitary response in the sheep fetus (Cuthrell et al). 1990;163:170-4
Pituitary gland
Antiprogestin treatment decreases midluteal luteinizing hormone pulse amplitude and primarily exerts a pituitary inhibition (Shoupe et al). 1990;163:1982-5
Pituitary gland, animal
The effect of adrenocorticotropic hormone infusion on subsequent pituitary response in the sheep fetus (Cuthrell et al). 1990;163:170-4
Pituitary hormone release inhibiting hormones
Efficacy and safety considerations in women with uterine leiomyomas treated with gonadotropin-releasing hormone agonists: the estrogen threshold hypothesis (Friedman et al). 1990;163:1114-9 (Clin. opinion)
Pituitary hormone releasing hormones
The effect of large uterine fibroids on urinary bladder function symptoms (Langer et al). 1990;163:1139-41
Efficacy and safety of intravenous pulsatile gonadotropin-releasing hormone: Lutrepulse for injection (Santoro). 1990;163:1759-64 (Supplement)
The GnRH pulse generator (Knobil). 1990;163:1721-6 (Supplement)
Gonadotropin-releasing hormone deficiency in men: diagnosis and treatment with exogenous gonadotropin-releasing hormone (Crowley and Whitcomb). 1990;163:1752-8 (Supplement)
Hypothalamic amenorrhea: clinical perspectives, pathophysiology, and management (Liu). 1990;163:1732-6 (Supplement)
The luteinizing hormone–releasing hormone pulse generator in men: abnormalities and clinical management (Matsumoto et al). 1990;163:1743-51 (Supplement)
Nature of gonadotropin-releasing hormone self-priming of luteinizing hormone secretion during the normal menstrual cycle (Sollenberger et al). 1990;163:1529-34
Neuromodulatory regulation of gonadotropin-releasing hormone pulsatile discharge in women (Jaffe et al). 1990;163:1727-31 (Supplement)
Polycystic ovary syndrome: abnormalities and management with pulsatile gonadotropin-releasing hormone and gonadotropin-releasing hormone analogs (Filicori et al). 1990;163:1737-42 (Supplement)
Practical aspects of pulsatile gonadotropin-releasing hormone administration (Schriock). 1990;163:1765-70 (Supplement)
Pulsatile GnRH in clinical medicine: introductory remarks (Jaffe and Yen). 1990;163:1719-20 (Supplement)
Pituitary hormone releasing hormones, analogs and derivatives
Effects of danazol, gonadotropin-releasing hormone agonist, and a combination of danazol and gonadotropin-releasing hormone agonist on experimental endometriosis (Sakata et al). 1990;163:1679-84
Efficacy and safety of intravenous pulsatile gonadotropin-releasing hormone: Lutrepulse for injection (Santoro). 1990;163:1759-64 (Supplement)
Polycystic ovary syndrome: abnormalities and management with pulsatile gonadotropin-releasing hormone and gonadotropin-releasing hormone analogs (Filicori et al). 1990;163:1737-42 (Supplement)
Practical aspects of pulsatile gonadotropin-releasing hormone administration (Schriock). 1990;163:1765-70 (Supplement)
Placenta
Changes in active and latent collagenase in human placenta around the time of parturition (Rajabi et al). 1990;163:499-503
The effect of nifedipine therapy on fetal and placental Doppler waveforms in preeclampsia remote from term (Moretti et al). 1990;163:1844-8
Immunocytochemical distribution and localization of 15-hydroxyprostaglandin dehydrogenase in human fetal membranes, decidua, and placenta (Cheung et al). 1990;163:1445-9
Interleukin-1β, human leukocyte antigen DR1, and transforming growth factor-β expression in endometrium, placenta, and placental membranes (Kauma et al). 1990;163:1430-7
Mechanism of action of interleukin-1β in increasing corticotropin-releasing factor and adrenocorticotropin hormone release from cultured human placental cells (Petraglia et al). 1990;163:1307-12
Metabolism of cocaine by human placentas: implications for fetal exposure (Roe et al). 1990;163:715-8
Placental histology in fetuses between 18 and 23 weeks' gestation with abnormal karyotype (Kuhlmann et al). 1990;163:1264-70
Preterm delivery: a risk factor for retained placenta (Romero et al). 1990;163:823-5
Response of placental vasculature to high glucose levels in the isolated human placental cotyledon (Roth et al). 1990;163:1828-30
Second-trimester placental biopsy for rapid fetal karyotyping (Cameron et al). 1990;163:931-4
Ultrastructural aspects of preeclampsia. II. Mitochondrial changes (Shanklin and Sibai). 1990;163:943-53
Why all placentas should be examined by a pathologist in 1990 (Salafia and Vintzileos). 1990;163:1282-93 (Curr. dev.)
Placenta, animal
Does the umbilical artery systolic/diastolic ratio reflect flow or acidosis? (Copel et al). 1990;163:751-6
Placental thromboxane and prostacyclin production in an ovine diabetic model (Dickinson et al). 1990;163:1831-5
Placenta accreta
Catastrophic complications of previous cesarean section (Chazotte and Cohen). 1990;163:738-42
Ultrasonographic evaluation of uteroplacental blood flow patterns of abnormally located and adherent placentas (Guy et al). 1990;163:723-7
Placenta diseases
The association of maternal floor infarction of the placenta with adverse perinatal outcome (Andres et al). 1990;163:935-8
Lack of specific placental abnormality associated with cocaine use (Gilbert et al). 1990;163:998-9
Spontaneous infarction of placental chorioangioma and associated regression of hydrops fetalis (Chazotte et al). 1990;163:1180-1
Ultrasonographic assessment of placental abnormalities (Jauniaux and Campbell). 1990;163:1650-8
Ultrasonographic diagnosis of a large placental intervillous thrombosis associated with elevated maternal serum α-fetoprotein level (Jauniaux et al). 1990;163:1558-60
Ultrasonographic evaluation of uteroplacental blood flow patterns of abnormally located and adherent placentas (Guy et al). 1990;163:723-7

Placenta praevia
Color flow Doppler—a useful instrument in the diagnosis of vasa previa (Harding et al). 1990;163:1566-8
Ultrasonographic evaluation of uteroplacental blood flow patterns of abnormally located and adherent placentas (Guy et al). 1990;163:723-7
Placental intervillous thrombosis; *see* **Thrombosis**
Plasma calcium; *see* **Calcium**
Plasma volume
Interrelationship between atrial natriuretic factor concentrations and acute volume expansion in pregnant and nonpregnant women (Hatjis et al). 1990;163:45-50
Plasminogen activator, tissue-type
Emergency treatment with recombinant tissue plasminogen activator of pulmonary embolism in a pregnant woman with antithrombin III deficiency (Baudo et al). 1990;163:1274-5
Enhanced generation and resolution of fibrin in women above the age of 30 years using oral contraceptives low in estrogen (Gram et al). 1990;163:438-42 (Supplement)
Platelet activating factor
Platelet activating factor enhances in vitro fertilization of rabbit oocytes (Roudebush et al). 1990;163:1670-3
Platelets; *see* **Blood platelets**
Pneumonia
Risk factors associated with the increasing prevalence of pneumonia during pregnancy (Berkowitz and LaSala). 1990;163:981-5
Polycystic ovary syndrome
Evidence of heterogeneous mechanisms in lipoprotein lipid alterations in hyperandrogenic women (Wild et al). 1990;163:1998-2005
Polycystic ovary syndrome: abnormalities and management with pulsatile gonadotropin-releasing hormone and gonadotropin-releasing hormone analogs (Filicori et al). 1990;163:1737-42 (Supplement)
Practical aspects of pulsatile gonadotropin-releasing hormone administration (Schriock). 1990;163:1765-70 (Supplement)
Specific binding sites for insulin-like growth factor I in the ovarian stroma of women with polycystic ovarian disease and stromal hyperthecosis (Nagamani and Stuart). 1990;163:1992-7
Suppression of serum insulin level by diazoxide does not alter serum testosterone of sex hormone–binding globulin levels in healthy, nonobese women (Nestler et al). 1990;163:1243-6
Polyhydramnios; *see* **Hydramnios**
Ponderal index; *see* **Fetal development**
Postmenopausal bleeding; *see* **Menopause**
Postoperative complications, animal
Adhesion formation after ovarian wound repair in New Zealand white rabbits: a comparison of ovarian microsurgical closure with ovarian nonclosure (Wiskind et al). 1990;163:1674-8
Postpartum hemorrhage
Hyperadrenergic orthostatic intolerance as a result of postpartum blood loss (Mader et al). 1990;163:1578-9
Postpartum period; *see* **Puerperium**
Pre-eclampsia
Eclampsia. VI. Maternal-perinatal outcome in 254 consecutive cases (Sibai). 1990;163:1049-55
The effect of nifedipine therapy on fetal and placental Doppler waveforms in preeclampsia remote from term (Moretti et al). 1990;163:1844-8
Effects of hypertension on pregnancy monitoring and results (Lenox et al). 1990;163:1173-9
Effects of magnesium and isradipine on contractile activation induced by the thromboxane A_2 analog U46619 in human uteroplacental arteries in term pregnancy (Skajaa et al). 1990;163:1323-33
Epidemiology of preeclampsia and eclampsia in the United States, 1979-1986 (Saftlas et al). 1990;163:460-5
Growth factor activity in the blood of women in whom preeclampsia develops is elevated from early pregnancy (Taylor et al). 1990;163:1839-44
Longitudinal study of the renin-angiotensin-aldosterone system in hypertensive pregnant women: deviations related to the development of superimposed preeclampsia (August et al). 1990;163:1612-21
Low-dose aspirin. II. Relationship of angiotensin II pressor responses, circulating eicosanoids, and pregnancy outcome (Brown et al). 1990;163:1853-61
Magnesium supplementation in pregnancy (Spätling and Fallenstein) (Letter); (Sibai) (Reply). 1990;163:240-1
National High Blood Pressure Education Program Working Group report on high blood pressure in pregnancy. 1990;163:1691-712 (Supplement)
The natural history of thrombocytopenia associated with preeclampsia (Katz et al). 1990;163:1142-3
Plasma atrial arginine vasopressin levels vary little between preeclamptic and control patients (Elias and Varizi). 1990;163:245 (Letter)
Preeclampsia in diabetic pregnancies (Garner et al). 1990;163:505-8
Preeclampsia—An endothelial cell disorder plus "something else"? (Liston and Kilpatrick) (Letter); (Roberts and Taylor) (Reply). 1990;163:1365-6
Pregnancy-induced hypertension and acute fatty liver of pregnancy: atypical presentations (Brown et al). 1990;163:1154-6
A protocol for managing severe preeclampsia in the second trimester (Sibai et al). 1990;163:733-8
Ultrastructural aspects of preeclampsia. II. Mitochondrial changes (Shanklin and Sibai). 1990;163:943-53
Zinc, preeclampsia, and γ-aminobutyric acid (Brophy). 1990;163:242-3 (Letter)
Pre-eclampsia syndromes, epidemiology
Epidemiology of preeclampsia and eclampsia in the United States, 1979-1986 (Saftlas et al). 1990;163:460-5
Predictive value of tests
Evaluation of a risk scoring system as a predictor of preterm birth in an indigent population (Owen et al). 1990;163:873-9
Measures of test performance and predictive values (Kadar) (Letter); (Schiff et al) (Reply). 1990;163:1374-5
Prediction of risk for preterm delivery by ultrasonographic measurement of cervical length (Andersen et al). 1990;163:859-67
Prevalence and etiology of respiratory distress in infants of diabetic mothers: predictive value of fetal lung maturation tests (Kjos et al). 1990;163:898-903
Prednisone
Intrapartum uterine rupture and inflammatory bowel disease (Peterson and Braak). 1990;163:1247-8
Preembryo biopsy; *see* **Biopsy**
Preembryo donation; *see* **Infertility, female**
Pregnancy
Assessment of cerebral hemodynamics in pregnant women

by internal carotid artery pulsed Doppler velocimetry (Ikeda and Mori). 1990;163:494-8
Blood pressure measured telemetrically from home throughout pregnancy (Mooney et al). 1990;163:30-6
Calcium supplementation during pregnancy may reduce preterm delivery in high-risk populations (Villar and Repke). 1990;163:1124-31
The course of labor after endurance exercise during pregnancy (Clapp). 1990;163:1799-805
Direct ultrasonographic measurement of fetal lung length in normal pregnancies and pregnancies complicated by prolonged rupture of membranes (Roberts and Mitchell). 1990;163:1560-6
The effect of physical activity during pregnancy on preterm delivery and birth weight (Klebanoff et al). 1990;163:1450-6
Interrelationship between atrial natriuretic factor concentrations and acute volume expansion in pregnant and nonpregnant women (Hatjis et al). 1990;163:45-50
Lymphokine production during term human pregnancy: differences between peripheral leukocytes and decidual cells (Dudley et al). 1990;163:1890-3
Magnesium supplementation in pregnancy (Spätling and Fallenstein) (Letter); (Sibai) (Reply). 1990;163:240-1
Neonatal morphometrics after endurance exercise during pregnancy (Clapp and Capeless). 1990;163:1805-11
Use of serial human chorionic gonadotropin measurements to differentiate between intrauterine and ectopic pregnancies (Kadar) (Letter); (Lindblom et al) (Reply). 1990;163:259-61

Pregnancy, abdominal

An abdominal pregnancy 10 years after treatment for pelvic tuberculosis (Durukan et al). 1990;163:594-5

Pregnancy, animal

Alteration of 24-hour rhythms in myometrial activity in the chronically catheterized pregnant rhesus monkey after a 6-hour shift in the light-dark cycle (Figueroa et al). 1990;163:648-54
Embryofetal effects of pentamidine isethionate administered to pregnant Sprague-Dawley rats (Harstad et al). 1990;163:912-6
Inhibition of spontaneous uterine contractions during the last trimester in pregnant baboons by an oxytocin antagonist (Wilson et al). 1990;163:1875-82
Maternal and uteroplacental hemodynamic effects of chronic captopril in the hypertensive, term-pregnant rat (Mabie et al). 1990;163:1861-7
Relationship between the ovine fetal umbilical artery blood flow waveform and umbilical vascular resistance (Irion and Clark). 1990;163:222-9
Role of the endothelium in adrenergic responses of mesenteric artery rings of pregnant rats (Parent et al). 1990;163:229-34
Transplacental transfer of zidovudine in the near-term pregnant baboon (Hankins et al). 1990;163:728-32

Pregnancy, ectopic

An abdominal pregnancy 10 years after treatment for pelvic tuberculosis (Durukan et al). 1990;163:594-5
Caution in use of new test for ectopic pregnancy (Haas) (Letter); (Lindblom et al) (Reply). 1990;163:694-5
Changes in the incidence of ectopic pregnancy in Hungary (Jakobovits) (Letter); (Mäkinen et al) (Reply). 1990;163:265-6
Conservative management of cervical pregnancy with subsequent fertility (Ayromlooi) (Letter); (Bachus) (Reply). 1990;163:1093-5
Conservative treatment of ovarian pregnancy by local prostaglandin $F_{2\alpha}$ injection (Koike et al). 1990;163:696 (Letter)
Contraception and ectopic pregnancy risk (Franks et al). 1990;163:1120-3
Corpus luteum function in early pregnancies is primarily determined by the rate of change of human chorionic gonadotropin levels (Kratzer and Taylor). 1990;163:1497-502
Critical comments on the treatment of tubal pregnancy with prostaglandins (Dietl and Lippert) (Letter); (Egarter and Husslein) (Reply). 1990;163:707-8
Embryo migration responsible for ectopic pregnancies (Rizk). 1990;163:1369 (Letter)
Heterotopic pregnancy associated with assisted reproductive technology (Dimitry et al). 1990;163:244-5 (Letter)
Laparoscopic diagnosis and treatment of interstitial ectopic pregnancy: a case report (Pasic and Wolfe). 1990;163:587-8
Mifepristone (RU 486) failure in an ovarian heterotopic pregnancy (Levin et al). 1990;163:543-4
Ovarian pregnancy: a report of 20 cases in one institution (Raziel et al). 1990;163:1182-5
Transabdominal and transvaginal ultrasonography in the diagnosis of ectopic pregnancy: a comparative study (Kivikoski et al). 1990;163:123-8
Treatment of cervical pregnancy with methotrexate (Sherer) (Letter); (Palti) (Reply). 1990;163:693-4
Use of serial human chorionic gonadotropin measurements to differentiate between intrauterine and ectopic pregnancies (Kadar) (Letter); (Lindblom et al) (Reply). 1990;163:259-61
Vaginal probe ultrasonography and ectopic pregnancy (Goldstein) (Letter); (Stiller) (Reply). 1990;163:1099-100

Pregnancy, multiple

Credit neonatal or obstetric care? (Weissman and Jakobi) (Letter); (Milligan) (Reply). 1990;163:1716
Prognosis for twins with birth weight <1500 gm: the impact of cesarean section in relation to fetal presentation (Rydhström). 1990;163:528-33

Pregnancy, prolonged

Observations on the cause of oligohydramnios in prolonged pregnancy (Trimmer et al). 1990;163:1900-3
Prolongation of pregnancy and survival of second twin (Goodlin) (Letter); (Feichtinger) (Reply). 1990;163:270-1

Pregnancy, prolonged, animal

A mechanism leading to reduced lung expansion and lung hypoplasia in fetal sheep during oligohydramnios (Harding et al). 1990;163:1904-13

Pregnancy complications

Acromegaly first diagnosed in pregnancy: the role of bromocriptine therapy (Yap et al). 1990;163:477-8
Antiphospholipid antibodies and recurrent pregnancy loss: correlation between the activated partial thromboplastin time and antibodies against phosphatidylserine and cardiolipin (Rote et al). 1990;163:575-84
Direct ultrasonographic measurement of fetal lung length in normal pregnancies and pregnancies complicated by prolonged rupture of membranes (Roberts and Mitchell). 1990;163:1560-6
The effect of adjusting maternal serum α-fetoprotein levels for maternal weight in pregnancies with fetal open spina bifida (Johnson et al). 1990;163:9-11

Pregnancy complications—cont'd
Emergency treatment with recombinant tissue plasminogen activator of pulmonary embolism in a pregnant woman with antithrombin III deficiency (Baudo et al). 1990;163:1274-5
Growth factor activity in the blood of women in whom preeclampsia develops is elevated from early pregnancy (Taylor et al). 1990;163:1839-44
Is indicated or spontaneous preterm delivery more advantageous for the fetus? (Owen et al). 1990;163:868-72
Ketoconazole treatment of Cushing's syndrome in pregnancy (Divers). 1990;163:1101 (Letter)
Lack of specific placental abnormality associated with cocaine use (Gilbert et al). 1990;163:998-9
Maternal serum α-fetoprotein level useful screening test (Lao). 1990;163:240 (Letter)
Pemphigus in pregnancy (Metzker and Merlob) (Letter); (Kanwar and Kaur) (Reply). 1990;163:1097
Pregnancy in a patient with treated Wilson's disease: a case report (Dupont et al). 1990;163:1527-8
Pregnancy-induced hypertension and acute fatty liver of pregnancy: atypical presentations (Brown et al). 1990;163:1154-6
Prevalence of use of cocaine and other substances in an obstetric population (Matera et al). 1990;163:797-801
Recurrent acute fatty liver of pregnancy (Barton et al). 1990;163:534-8
Toxicity of vancomycin given during pregnancy (Gouyon and Petion) (Letter); (Reyes and Ostrea) (Reply). 1990;163:1375-6

Pregnancy complications, cardiovascular
β-Adrenergic receptor blockade in the management of pregnant women with mitral stenosis (Al Kasab et al). 1990;163:37-40
Effect of mitral valve prosthetic surgery on the outcome of a growth-retarded fetus: a case report (Izquierdo et al). 1990;163:584-7
Effect of uterine contractility and maternal hypotension on prolonged decelerations after bupivacaine epidural anesthesia (Steiger and Nageotte). 1990;163:808-12
Epidemiology of preeclampsia and eclampsia in the United States, 1979-1986 (Saftlas et al). 1990;163:460-5
Fetal umbilical artery Doppler response to graded maternal aerobic exercise and subsequent maternal mean arterial blood pressure: predictive value for pregnancy-induced hypertension (Hume et al). 1990;163:826-9
Intracellular sodium levels in pregnant women with hypertension (Goodlin) (Letter); (Sowers and Zemel) (Reply). 1990;163:261-2
Laboratory identification of the lupus anticoagulant in normal pregnancy and pregnancy-induced hypertension (Riveros et al) (Letter); (Lockwood) (Reply). 1990;163:704-5
Longitudinal study of the renin-angiotensin-aldosterone system in hypertensive pregnant women: deviations related to the development of superimposed preeclampsia (August et al). 1990;163:1612-21
Magnesium sulfate and promethazine do not interact to cause hypotension in gravid ewes (Pollack et al). 1990;163:787-94
National High Blood Pressure Education Program Working Group report on high blood pressure in pregnancy. 1990;163:1691-712 (Supplement)
National High Blood Pressure Education Program Working Group report on high blood pressure in pregnancy: foreword (Lenfant et al). 1990;163:1689-90 (Supplement)

Pregnancy complications, cardiovascular, animal
Fetal and maternal response to intravenous infusion of a thromboxane synthetase inhibitor (Cardin et al). 1990;163:1345-9

Pregnancy complications, hematologic
Effects of hypertension on pregnancy monitoring and results (Lenox et al). 1990;163:1173-9
HELLP does not always mean immediate HELP! (Goodlin) (Letter); (Sibai) (Reply). 1990;163:1089
Liver histopathologic findings in women with sickle cell disease given prophylactic transfusion during pregnancy (Yeomans et al). 1990;163:958-64
Low fetal risks in pregnancies associated with idiopathic thrombocytopenia purpura (Burrows and Kelton). 1990;163:1147-50
The natural history of thrombocytopenia associated with preeclampsia (Katz et al). 1990;163:1142-3
A reappraisal of the need for autologous blood donation in the obstetric patient (Andres et al). 1990;163:1551-3

Pregnancy complications, infectious
Cervicovaginal microflora and pregnancy outcome: results of a double-blind, placebo-controlled trial of erythromycin treatment (McGregor et al). 1990;163:1580-91
Detection of congenital toxoplasmosis by chorionic villus sampling and early amniocentesis (Foulon et al). 1990;163:1511-3
Drug prophylaxis for human immunodeficiency virus–infected pregnant women: ethical considerations (Minkoff and Moreno). 1990;163:1111-4 (Clin. opinion)
False-negative syphilis screening: the prozone phenomenon, nonimmune hydrops, and diagnosis of syphilis during pregnancy (Berkowitz et al). 1990;163:975-7
High infectious morbidity in pregnant women with insulin-dependent diabetes: an understated complication (Stamler et al). 1990;163:1217-21
Intrapartum hepatitis B screening in a low-risk population (Ernest et al). 1990;163:978-80
Intrauterine *Listeria* infection: prenatal diagnosis by biophysical assessment and amniocentesis (Liner). 1990;163:1596-7
Management and outcomes of pregnancies complicated by human B19 parvovirus infection: a prospective study (Rodis et al). 1990;163:1168-71
Risk factors associated with the increasing prevalence of pneumonia during pregnancy (Berkowitz and LaSala). 1990;163:981-5
Risk factors for perinatal group B streptococcal disease after amniotic fluid colonization (Silver et al). 1990;163:19-25

Pregnancy complications, neoplastic
Cervical cancer: Role for progesterone during pregnancy and contraception? (Stendahl and Rogo). 1990;163:685-6 (Letter)
Colon cancer in pregnancy with elevated maternal serum α-fetoprotein level at presentation (Gonsoulin et al). 1990;163:1172-3
Multiple endocrine adenomatosis type I in pregnancy (Smythe et al). 1990;163:1037-9
Perception of teratogenic risk by pregnant women exposed to diagnostic radiation during pregnancy (Mastroiacovo et al) (Letter); (Koren) (Reply). 1990;163:695-6
Systemic cystic angiomatosis in pregnancy: a case presentation and review of the literature (Bardeguez et al). 1990;163:42-5

Pregnancy in diabetes
Absence of evidence of pulmonary maturity at amniocen-

tesis in term infants of diabetic mothers (Ojomo and Coustan). 1990;163:954-7
Ascertainment bias in diabetic outcome data (FitzSimmons and Davidson) (Letter); (Damm and Mølsted-Pedersen) (Reply). 1990;163:682-3
Correlations between antepartum maternal metabolism and newborn behavior (Rizzo et al). 1990;163:1458-64
Does fasting interval affect the glucose challenge test? (Berkus et al). 1990;163:1812-7
Effect of low-dose oral contraceptives on carbohydrate and lipid metabolism in women with recent gestational diabetes: results of a controlled, randomized, prospective study (Kjos et al). 1990;163:1822-7
Findings not new (Abell and Beischer) (Letter); (Langer) (Reply). 1990;163:2027-8
Gestational diabetes mellitus: the prevalence of glucose intolerance and diabetes mellitus in the first two months post partum (Kjos et al). 1990;163:93-8
Glucose tolerance in pregnancy: ethnic variation and influence of body habitus (Green et al). 1990;163:86-92
High infectious morbidity in pregnant women with insulin-dependent diabetes: an understated complication (Stamler et al). 1990;163:1217-21
Infants of diabetic mothers with accelerated fetal growth by ultrasonography: Are they all alike? (Keller et al). 1990;163:893-7
Long-term maternal-fetal exposure to high-low insulin concentrations alter liver but not brain insulin receptors (Devaskar et al). 1990;163:1350-6
Maternal serum α-fetoprotein levels in pregnancies complicated by diabetes: implications for screening programs (Martin et al). 1990;163:1209-16
Outpatient obstetric management of women with type I diabetes (Bourgeois and Duffer). 1990;163:1065-73
Placental thromboxane and prostacyclin production in an ovine diabetic model (Dickinson et al). 1990;163:1831-5
Preeclampsia in diabetic pregnancies (Garner et al). 1990;163:505-8
Prevalence and etiology of respiratory distress in infants of diabetic mothers: predictive value of fetal lung maturation tests (Kjos et al). 1990;163:898-903
Relationships between glucose levels and insulin secretion during a glucose challenge test (Berkus et al). 1990;163:1818-21
Response of placental vasculature to high glucose levels in the isolated human placental cotyledon (Roth et al). 1990;163:1828-30

Pregnancy loss; *see* **Abortion**; **Pregnancy outcome**

Pregnancy outcome

Antiphospholipid antibodies and recurrent pregnancy loss: correlation between the activated partial thromboplastin time and antibodies against phosphatidylserine and cardiolipin (Rote et al). 1990;163:575-84
The association of maternal floor infarction of the placenta with adverse perinatal outcome (Andres et al). 1990;163:935-8
Cervicovaginal microflora and pregnancy outcome: results of a double-blind, placebo-controlled trial of erythromycin treatment (McGregor et al). 1990;163:1580-91
Chronic renal disease and pregnancy outcome (Cunningham et al). 1990;163:453-9
A comparison of tocolysis with nifedipine or ritodrine: analysis of efficacy and maternal, fetal, and neonatal outcome (Ferguson et al). 1990;163:105-11
Credit neonatal or obstetric care? (Weissman and Jakobi) (Letter); (Milligan) (Reply). 1990;163:1716
The diagnostic values of concurrent nonstress testing, amniotic fluid measurement, and Doppler velocimetry in screening a general high-risk population (Devoe et al). 1990;163:1040-8
Eclampsia. VI. Maternal-perinatal outcome in 254 consecutive cases (Sibai). 1990;163:1049-55
The effect of mode of delivery on the perinatal outcome in fetuses with abdominal wall defects (Moretti et al). 1990;163:833-8
Effects of hypertension on pregnancy monitoring and results (Lenox et al). 1990;163:1173-9
Inhibitory cofactor of antiphospholipid antibody in normal pregnancy sera (Cheng). 1990;163:701 (Letter)
Low-dose aspirin. II. Relationship of angiotensin II pressor responses, circulating eicosanoids, and pregnancy outcome (Brown et al). 1990;163:1853-61
Management and outcomes of pregnancies complicated by human B19 parvovirus infection: a prospective study (Rodis et al). 1990;163:1168-71
Maternal exercise and early pregnancy outcome (Suzuki and Miller). 1990;163:1103 (Letter)
Perinatal outcome of forty-nine pregnancies complicated by acardiac twinning (Moore et al). 1990;163:907-12
Perinatal survival with expectant management of midtrimester rupture of membranes (Major and Kitzmiller). 1990;163:838-44
Pregnancy in a patient with treated Wilson's disease: a case report (Dupont et al). 1990;163:1527-8
Pregnancy outcomes among mothers infected with human immunodeficiency virus and uninfected control subjects (Minkoff et al). 1990;163:1598-604
Prognostic indicators of the resolution of nonimmune hydrops fetalis and survival of the fetus (Carlson et al). 1990;163:1785-7
Recurrent adverse pregnancy outcome and antiphospholipid antibodies (Reece et al). 1990;163:162-9 (Curr. dev.)
Reducing cesarean sections at a teaching hospital (Sanchez-Ramos et al). 1990;163:1081-8
Risk factors associated with the increasing prevalence of pneumonia during pregnancy (Berkowitz and LaSala). 1990;163:981-5
The stuck twin phenomenon: Ultrasonographic findings, pregnancy outcome, and management with serial amniocenteses (Mahony et al). 1990;163:1513-22

Pregnancy trimester, first

Corpus luteum function in early pregnancies is primarily determined by the rate of change of human chorionic gonadotropin levels (Kratzer and Taylor). 1990;163:1497-502
Early pregnancy failure—appropriate terminology (Goldstein). 1990;163:1093 (Letter)
Inhibition of aromatase activity by 8-bromo-cyclic adenosine monophosphate in cultured first-trimester human trophoblast (Rodway et al). 1990;163:1546-51
Soluble factors produced by isolated first-trimester chorionic villi directly inhibit proliferation of T cells (Silver et al). 1990;163:1914-9
Transvaginal ultrasonographic detection of congenital anomalies in the first trimester (Cullen et al). 1990;163:466-76
Ultrasonographic dating of very early pregnancy (Cadkin and McAlpin-Cadkin). 1990;163:1103 (Letter)

Pregnancy trimester, second
Direct analysis of uncultured cytotrophoblastic cells from second- and third-trimester placentas: an accurate and rapid method for detection of fetal chromosome abnormalities (Shulman et al). 1990;163:1606-9
Intraamniotic infection in the very early phase of the second trimester (Goldstein et al). 1990;163:1261-3
Perinatal survival with expectant management of midtrimester rupture of membranes (Major and Kitzmiller). 1990;163:838-44
A protocol for managing severe preeclampsia in the second trimester (Sibai et al). 1990;163:733-8
Second-trimester placental biopsy for rapid fetal karyotyping (Cameron et al). 1990;163:931-4
Second-trimester ultrasonography: determinants of visualization of fetal anatomic structures (Catanzarite and Quirk). 1990;163:1191-5
Ultrasonographic detection of the second-trimester fetus with trisomy 18 and trisomy 21 (Ginsberg et al). 1990;163:1186-90
Pregnancy trimester, third
Direct analysis of uncultured cytotrophoblastic cells from second- and third-trimester placentas: an accurate and rapid method for detection of fetal chromosome abnormalities (Shulman et al). 1990;163:1606-9
Inhibition of spontaneous uterine contractions during the last trimester in pregnant baboons by an oxytocin antagonist (Wilson et al). 1990;163:1875-82
Placental histology in fetuses between 18 and 23 weeks' gestation with abnormal karyotype (Kuhlmann et al). 1990;163:1264-70
Premature infant; *see* **Infant, premature**
Premature labor; *see* **Labor, premature**
Premature rupture of membranes; *see* **Fetal membranes, premature rupture**
Premenstrual syndrome
Vitamin E levels in premenstrual syndrome (Chuong et al). 1990;163:1591-5
Prenatal care
The relationship of cocaine use to syphilis and human immunodeficiency virus infections among inner city parturient women (Minkoff et al). 1990;163:521-6
Prenatal diagnosis
The associated anomalies that determine prognosis in congenital omphaloceles (Tucci and Bard). 1990;163:1646-9
Color flow Doppler—a useful instrument in the diagnosis of vasa previa (Harding et al). 1990;163:1566-8
Detection of congenital toxoplasmosis by chorionic villus sampling and early amniocentesis (Foulon et al). 1990;163:1511-3
Diagnosis and management of prenatally detected myelomeningocele: a preliminary report (Hogge et al). 1990;163:1061-5
Direct analysis of uncultured cytotrophoblastic cells from second- and third-trimester placentas: an accurate and rapid method for detection of fetal chromosome abnormalities (Shulman et al). 1990;163:1606-9
Direct ultrasonographic measurement of fetal lung length in normal pregnancies and pregnancies complicated by prolonged rupture of membranes (Roberts and Mitchell). 1990;163:1560-6
An evaluation of the chorionic villus sampling learning curve (Silver et al). 1990;163:917-22
In utero detection of cardiac failure from an aneurysm of the vein of Galen (Jeanty et al). 1990;163:50-1
Intrauterine *Listeria* infection: prenatal diagnosis by biophysical assessment and amniocentesis (Liner). 1990;163:1596-7
Potential prenatal predictions of Down syndrome: a statistical analysis (O'Brien et al). 1990;163:1796-8
Prenatal diagnosis of a chest wall mass with ultrasonography and Doppler velocimetry: a case report (Smith et al). 1990;163:567-9
Prenatal diagnosis of congenital cytomegalovirus infection: two decades later (Grose and Weiner). 1990;163:447-50 (Clin. opinion)
Prenatal diagnosis of congenital cytomegalovirus infection by virus isolation from amniotic fluid (Weiner and Grose). 1990;163:1253-5
Prenatal diagnosis of fetal intracranial calcifications (Koga et al). 1990;163:1543-5
Prenatal diagnosis of laryngeal atresia (Watson et al). 1990;163:1456-7
Prognostic indicators of the resolution of nonimmune hydrops fetalis and survival of the fetus (Carlson et al). 1990;163:1785-7
Reliability of ultrasonographic formulary in the prediction of fetal weight and survival of very-low-birth-weight infants (Mills et al). 1990;163:1568-74
Screening for trisomy 21 with ultrasonographic determination of biparietal diameter/femur length ratio (Marquette et al). 1990;163:1604-5
Transcervical chorionic villus sampling and amniocentesis: a comparison of reliability, culture findings, and fetal outcome (Ferguson et al). 1990;163:926-31
Transvaginal ultrasonographic detection of congenital anomalies in the first trimester (Cullen et al). 1990;163:466-76
Ultrasonographic assessment of placental abnormalities (Jauniaux and Campbell). 1990;163:1650-8
Ultrasonographic diagnosis of a large placental intervillous thrombosis associated with elevated maternal serum α-fetoprotein level (Jauniaux et al). 1990;163:1558-60
Presidential address
Presidential address. 1990;163:1000-6
Preterm labor; *see* **Labor, premature**
Primiparity; *see* **Parity**
Prior surgery; *see* **Surgery, operative**
Procollagen
Collagen metabolism in gynecologic patients: changes in the concentration of the aminoterminal propeptide of type III procollagen in serum (Puistola et al). 1990;163:1276-81
Prodrugs
Prodrugs: Advantage or disadvantage? (Hammerstein). 1990;163:2198-203 (Symposium)
Professional practice
A chill wind blows: Webster, obstetrics, and the health of women (Chavkin and Rosenfield). 1990;163:450-2 (Clin. opinion)
Retrospection and prospection (McLeod). 1990;163:1000-6 (Pres. address)
Progestational hormones
Comparison of norethindrone and medroxyprogesterone acetate with natural progesterone and estradiol in stimulating prolactin production from cultured endometrial stromal cells (Levin et al). 1990;163:1932-8
Progestational hormones, antagonists and inhibitors
Antiprogestin treatment decreases midluteal luteinizing

hormone pulse amplitude and primarily exerts a pituitary inhibition (Shoupe et al). 1990;163:1982-5

Progestational hormones, synthetic
Binding of oral contraceptive progestogens to serum proteins and cytoplasmic receptor (Juchem and Pollow). 1990;163:2171-83 (Symposium)
The clinical relevance of oral contraceptive pill–induced plasma lipid changes: facts and fiction (Hoppe). 1990;163:388-91 (Supplement)
Comparative studies of 30 μg ethinyl estradiol combined with gestodene and desogestrel on blood coagulation, fibrinolysis, and platelets (Daly and Bonnar). 1990;163:430-7 (Supplement)
Metabolic changes during treatment with two different progestogens (Refn et al). 1990;163:374-7 (Supplement)
Prodrugs: Advantage or disadvantage? (Hammerstein). 1990;163:2198-203 (Symposium)
Serum pharmacokinetics of orally administered desogestrel and binding of contraceptive progestogens to sex hormone–binding globulin (Bergink et al). 1990;163:2132-7 (Symposium)

Progesterone
Binding of oral contraceptive progestogens to serum proteins and cytoplasmic receptor (Juchem and Pollow). 1990;163:2171-83 (Symposium)
Cervical cancer: Role for progesterone during pregnancy and contraception? (Stendahl and Rogo). 1990;163:685-6 (Letter)
Comparison of norethindrone and medroxyprogesterone acetate with natural progesterone and estradiol in stimulating prolactin production from cultured endometrial stromal cells (Levin et al). 1990;163:1932-8
Corpus luteum function in early pregnancies is primarily determined by the rate of change of human chorionic gonadotropin levels (Kratzer and Taylor). 1990;163:1497-502
Effects of oral contraceptives on carbohydrate and lipid metabolisms in a healthy population: the Telecom Study (Simon et al). 1990;163:382-7 (Supplement)
Effects on bone of surgical menopause and estrogen therapy with or without progesterone replacement in cynomolgus monkeys (Jayo et al). 1990;163:614-8
Luteal insufficiency: correlation between endometrial dating and integrated progesterone output in clomiphene citrate–induced cycles (Hecht et al). 1990;163:1986-91
Prodrugs: Advantage or disadvantage? (Hammerstein). 1990;163:2198-203 (Symposium)
Progesterone increases cardiovascular toxicity to cocaine in nonpregnant ewes (Plessinger and Woods). 1990;163:1659-64
A progesterone-induced blocking factor corrects high resorption rates in mice treated with antiprogesterone (Szekeres-Bartho et al). 1990;163:1320-1
Serum pharmacokinetics of orally administered desogestrel and binding of contraceptive progestogens to sex hormone–binding globulin (Bergink et al). 1990;163:2132-7 (Symposium)

Progestogens; *see* **Progestational hormones, synthetic**
Prohormones; *see* **Prodrugs**
Prolactin
Comparison of norethindrone and medroxyprogesterone acetate with natural progesterone and estradiol in stimulating prolactin production from cultured endometrial stromal cells (Levin et al). 1990;163:1932-8
Comparisons of glycosylated and nonglycosylated amniotic fluid prolactins in normal second- and third-trimester pregnancies (McCoshen et al). 1990;163:81-5

Prolongation of pregnancy; *see* **Pregnancy, prolonged**
Prolonged rupture of membranes; *see* **Fetal membranes, prolonged rupture**
Promethazine
Magnesium sulfate and promethazine do not interact to cause hypotension in gravid ewes (Pollack et al). 1990;163:787-94

Prostacyclins; *see* **Prostaglandins X**
Prostaglandin synthase
Immunohistochemical localization of prostaglandin H synthase in the female reproductive tract and endometriosis (Van Voorhis et al). 1990;163:57-62

Prostaglandins
Critical comments on the treatment of tubal pregnancy with prostaglandins (Dietl and Lippert) (Letter); (Egarter and Husslein) (Reply). 1990;163:707-8
Immunohistochemical localization of prostaglandin H synthase in the female reproductive tract and endometriosis (Van Voorhis et al). 1990;163:57-62
Low-dose aspirin. II. Relationship of angiotensin II pressor responses, circulating eicosanoids, and pregnancy outcome (Brown et al). 1990;163:1853-61
Morphologic study of changes of collagenous tissue in the amnion and cervix during prostaglandin-induced abortion and delivery (Manabe and Yoshida). 1990;163:52-6
Venous and hepatic vascular responses to indomethacin and prostaglandin E_1 in the fetal lamb (Paulick et al). 1990;163:1357-63

Prostaglandins E_2; *See* **Dinoprostone**
Prostaglandins $F_{2\alpha}$; *see* **Dinoprost**
Prostaglandins H
Immunohistochemical localization of prostaglandin H synthase in the female reproductive tract and endometriosis (Van Voorhis et al). 1990;163:57-62

Prostaglandins X
Placental thromboxane and prostacyclin production in an ovine diabetic model (Dickinson et al). 1990;163:1831-5

Prosthetic heart valves; *see* **Heart valve prosthesis**
Protein kinase C
Evidence of a role for protein kinase C in epidermal growth factor–induced prostaglandin E_2 synthesis in amnion cells (Kniss et al). 1990;163:1883-90

Puerperium
Gestational diabetes mellitus: the prevalence of glucose intolerance and diabetes mellitus in the first two months post partum (Kjos et al). 1990;163:93-8
Postpartum coronary artery dissection followed by heart transplantation (Curiel et al). 1990;163:538-9
Successful treatment of postpartum shock caused by amniotic fluid embolism with cardiopulmonary bypass and pulmonary artery thromboembolectomy (Esposito et al). 1990;163:572-4

Pulmonary artery, surgery
Successful treatment of postpartum shock caused by amniotic fluid embolism with cardiopulmonary bypass and pulmonary artery thromboembolectomy (Esposito et al). 1990;163:572-4

Pulmonary edema
Ritodrine infusion and cardiomyopathy (Caritis) (Letter); (Blickstein) (Reply). 1990;163:254-6

Pulmonary embolism
Emergency treatment with recombinant tissue plasminogen activator of pulmonary embolism in a pregnant woman

Pulmonary embolism—cont'd
with antithrombin III deficiency (Baudo et al). 1990;163:1274-5
Successful treatment of postpartum shock caused by amniotic fluid embolism with cardiopulmonary bypass and pulmonary artery thromboembolectomy (Esposito et al). 1990;163:572-4
Pulmonary surfactants
Prevalence and etiology of respiratory distress in infants of diabetic mothers: predictive value of fetal lung maturation tests (Kjos et al). 1990;163:898-903
Pulsatile oxytocin; *see* **Oxytocin**
Purpura, thrombocytopenic
Low fetal risks in pregnancies associated with idiopathic thrombocytopenia purpura (Burrows and Kelton). 1990;163:1147-50

Q

Quality assurance, health care
The impact of a quality assurance process on the frequency and confirmation rate of hysterectomy (Gambone et al). 1990;163:545-50
Questionnaires
Use of the T-ACE questions to detect risk-drinking (Elliot) (Letter); (Sokol) (Reply). 1990;163:684-5

R

Racial stocks
The effect of race on the relationship between fetal death and altered fetal growth (Ferguson and Myers). 1990;163:1222-30
Radiation effects
Hyperkalemia secondary to irradiation of packed red blood cells: possible effects with intravascular fetal transfusion (Thorp et al). 1990;163:607-9
Perception of teratogenic risk by pregnant women exposed to diagnostic radiation during pregnancy (Mastroiacovo et al) (Letter); (Koren) (Reply). 1990;163:695-6
Rapid eye movements; *see* **Sleep, REM**
Rats, inbred strains
Nifedipine enhances the cardiac toxicity of magnesium sulfate in the isolated perfused Sprague-Dawley rat heart (Thorp et al). 1990;163:655-6
Rats, Sprague-Dawley; *see* **Rats, inbred strains**
Raz procedure; *see* **Suspensions**
Receptors, adrenergic, beta
β-Adrenergic receptor blockade in the management of pregnant women with mitral stenosis (Al Kasab et al). 1990;163:37-40
Receptors, angiotensin
Changes in platelet angiotensin II binding sites associated with the human menstrual cycle (Baker et al). 1990;163:175-6
Receptors, estrogen, animal
Uterine artery estrogen receptors in the nonpregnant and pregnant guinea pig (Leiberman et al). 1990;163:1685-8
Receptors, glycoprotein
Epithelial cells from normal human endometrium express a tumor-associated glycoprotein (TAG-72) epitope in vitro (Osteen et al). 1990;163:479-84
Receptors, insulin
Long-term maternal-fetal exposure to high-low insulin concentrations alter liver but not brain insulin receptors (Devaskar et al). 1990;163:1350-6
Specific binding sites for insulin-like growth factor I in the ovarian stroma of women with polycystic ovarian disease and stromal hyperthecosis (Nagamani and Stuart). 1990;163:1992-7
Receptors, progesterone, animal
A progesterone-induced blocking factor corrects high resorption rates in mice treated with antiprogesterone (Szekeres-Bartho et al). 1990;163:1320-1
Receptors, steroid
Binding of oral contraceptive progestogens to serum proteins and cytoplasmic receptor (Juchem and Pollow). 1990;163:2171-83 (Symposium)
Recombinant tissue plasminogen activator; *see* **Plasminogen activator, tissue-type**
Recurrent pregnancy loss; *see* **Abortion, habitual**; **Pregnancy outcome**
Red cell alloimmunization; *see* **Erythrocytes, immunology**
Renal failure, chronic; *see* **Kidney failure, chronic**
Renin-angiotensin system
Longitudinal study of the renin-angiotensin-aldosterone system in hypertensive pregnant women: deviations related to the development of superimposed preeclampsia (August et al). 1990;163:1612-21
Reproducibility of results
Transcervical chorionic villus sampling and amniocentesis: a comparison of reliability, culture findings, and fetal outcome (Ferguson et al). 1990;163:926-31
Reproduction techniques
Ethics of new reproductive technologies (Blaskiewicz) (Letter); (Macnaughton) (Reply). 1990;163:1376
Heterotopic pregnancy associated with assisted reproductive technology (Dimitry et al). 1990;163:244-5 (Letter)
Residency; *see* **Internship and residency**
Respiratory distress syndrome
Digoxin-like immunoreactive factor and respiratory distress syndrome (Goodlin). 1990;163:1091 (Letter)
Prevalence and etiology of respiratory distress in infants of diabetic mothers: predictive value of fetal lung maturation tests (Kjos et al). 1990;163:898-903
Retained placenta; *see* **Placenta**
Retropubic suspension procedures; *see* **Suspensions**
Rh isoimmunization
Amniotic fluid midtrimester delta optical density measurements at 450 nm in Rh disease (Nelson) (Letter); (Queenan) (Reply). 1990;163:710-2
A case of Rh isoimmunization: Should threatened first-trimester abortion be an indication for Rh immune globulin prophylaxis? (Dayton et al). 1990;163:63-4
Effects of intravascular fetal blood transfusion on fetal intracardiac Doppler velocity waveforms (Rizzo et al). 1990;163:1231-8
The incidence of significant fetomaternal hemorrhage in patients undergoing cesarean section (Feldman et al). 1990;163:855-8
Placental transfer of cefazolin and piperacillin in pregnancies remote from term complicated by Rh isoimmunization (Brown et al). 1990;163:938-43
Postinjection kinetics of antepartum Rh immune globulin (Witter et al). 1990;163:784-6
Rhesus monkeys; *see* ***Macaca mulatta***
Risk factors
Antenatal microbiologic and maternal risk factors associated with prematurity (McGregor et al). 1990;163:1465-73
Bacterial vaginosis and trichomoniasis vaginitis are risk factors for cuff cellulitis after abdominal hysterectomy (Soper et al). 1990;163:1016-23
The diagnostic values of concurrent nonstress testing, am-

niotic fluid measurement, and Doppler velocimetry in screening a general high-risk population (Devoe et al). 1990;163:1040-8
Evaluation of a risk scoring system as a predictor of preterm birth in an indigent population (Owen et al). 1990;163:873-9
Maternal serum α-fetoprotein level useful screening test (Lao). 1990;163:240 (Letter)
Oral contraceptives in risk groups: Exclusion or monitoring? (Guillebaud). 1990;163:443-6 (Supplement)
Prediction of risk for preterm delivery by ultrasonographic measurement of cervical length (Andersen et al). 1990;163:859-67
Risk factors associated with the increasing prevalence of pneumonia during pregnancy (Berkowitz and LaSala). 1990;163:981-5
Risk factors for perinatal group B streptococcal disease after amniotic fluid colonization (Silver et al). 1990; 163:19-25
Risk factors for preterm premature rupture of fetal membranes: a multicenter case-control study (Harger et al). 1990;163:130-7
Risk factors for third-degree and fourth-degree perineal lacerations in forceps and vacuum deliveries (Combs et al). 1990;163:100-4
Smoking and the antioxidant ascorbic acid: plasma, leukocyte, and cervicovaginal cell concentrations in normal healthy women (Basu et al). 1990;163:1948-52
Use of the T-ACE questions to detect risk-drinking (Elliot) (Letter); (Sokol) (Reply). 1990;163:684-5

Ritodrine
Awaiting cervical change for the diagnosis of preterm labor does not compromise the efficacy of ritodrine tocolysis (Utter et al). 1990;163:882-6
A comparison of tocolysis with nifedipine or ritodrine: analysis of efficacy and maternal, fetal, and neonatal outcome (Ferguson et al). 1990;163:105-11
Effects of ritodrine tocolysis on cardiac isozymes and electrocardiography (Hendricks and Katz) (Letter); (Hadi and Albazzaz) (Reply). 1990;163:699-701
Ritodrine infusion and cardiomyopathy (Caritis) (Letter); (Blickstein) (Reply). 1990;163:254-6

Round ligament
Hemoperitoneum as a result of coital injury without associated vaginal injury (McColgin et al). 1990;163:1503-5

RU-486; *see* **Mifepristone**

Running
The course of labor after endurance exercise during pregnancy (Clapp). 1990;163:1799-805
Neonatal morphometrics after endurance exercise during pregnancy (Clapp and Capeless). 1990;163:1805-11

Rupture of uterus; *see* **Uterine rupture**

S

Sacrococcygeal region
Survival in a fetus with sacrococcygeal teratoma and hydrops (Nakayama). 1990;163:682 (Letter)

Saliva, analysis
Ovulation prediction from cyclic changes in salivary electrical conductivity (Loewit et al). 1990;163:708-10 (Letter)

Salpingectomy; *see* **Sterilization, tubal**

Salpingitis
Collagen metabolism in gynecologic patients: changes in the concentration of the aminoterminal propeptide of type III procollagen in serum (Puistola et al). 1990;163:1276-81

Sampling studies
An evaluation of the chorionic villus sampling learning curve (Silver et al). 1990;163:917-22

Sapphire probes; *see* **Surgical instruments**

Screening, genetic; *see* **Genetic screening**

Screening, mass; *see* **Mass screening**

Second trimester; *see* **Pregnancy trimester, second**

Selection bias
Ascertainment bias in diabetic outcome data (FitzSimmons and Davidson) (Letter); (Damm and Mølsted-Pedersen) (Reply). 1990;163:682-3

Self medication
Autogenic masculinization (Punch and Ansbacher). 1990;163:114-6

Semantics
A conceptual thought (Pearse). 1990;163:1098 (Letter)

Serology
False-negative syphilis screening: the prozone phenomenon, nonimmune hydrops, and diagnosis of syphilis during pregnancy (Berkowitz et al). 1990;163:975-7

Serum lipids; *see* **Lipids**

Sex characteristics
Autogenic masculinization (Punch and Ansbacher). 1990;163:114-6

Sex determination
Rapid determination of fetal sex (Stephens) (Letter); (Pinckert et al) (Reply). 1990;163:683-4

Sex hormone–binding globulin
Binding of oral contraceptive progestogens to serum proteins and cytoplasmic receptor (Juchem and Pollow). 1990;163:2171-83 (Symposium)
Metabolic changes during treatment with two different progestogens (Refn et al). 1990;163:374-7 (Supplement)
Pharmacokinetics of gestagens: some problems (Fotherby). 1990;163:323-8 (Supplement)
Pharmacokinetics of the contraceptive steroids levonorgestrel and gestodene after single and multiple oral administration to women (Kuhnz). 1990;163:2120-7 (Symposium)
Protein binding of active ingredients and comparison of serum ethinyl estradiol sex hormone–binding globulin, corticosteroid-binding globulin, and cortisol levels in women using a combination of gestodene/ethinyl estradiol (Femovan) or a combination of desogestrel/ethinyl estradiol (Marvelon) and single-dose ethinyl estradiol bioequivalence from both oral contraceptives (Hümpel et al). 1990;163:329-33 (Supplement)
Suppression of serum insulin level by diazoxide does not alter serum testosterone of sex hormone–binding globulin levels in healthy, nonobese women (Nestler et al). 1990;163:1243-6

Sex hormones; *see also* **Contraceptives, oral**
First European Conference on Sex Steroids and Metabolism: introductory remarks (Jespersen et al). 1990;163:273 (Supplement)
Human oocyte and preembryo donation: an evolving method for the treatment of infertility (Sauer and Paulson). 1990;163:1421-4 (Clin. opinion)
Impairment of glucose tolerance: mechanism of action and impact on the cardiovascular system (Beck-Nielsen et al). 1990;163:292-5 (Supplement)
Metabolic changes during treatment with two different progestogens (Refn et al). 1990;163:374-7 (Supplement)
Oral contraceptives in risk groups: Exclusion or monitoring? (Guillebaud). 1990;163:443-6 (Supplement)

Sex hormones—cont'd
Pharmacokinetics of gestagens: some problems (Fotherby). 1990;163:323-8 (Supplement)
Protein binding of active ingredients and comparison of serum ethinyl estradiol sex hormone–binding globulin, corticosteroid-binding globulin, and cortisol levels in women using a combination of gestodene/ethinyl estradiol (Femovan) or a combination of desogestrel/ethinyl estradiol (Marvelon) and single-dose ethinyl estradiol bioequivalence from both oral contraceptives (Hümpel et al). 1990;163:329-33 (Supplement)
Role of plasma lipoproteins in the pathogenesis of atherosclerotic disease, with special reference to sex hormone effects (Tikkanen). 1990;163:296-304 (Supplement)
Why do we need pharmacokinetic studies? (Hvidberg). 1990;163:316-8 (Supplement)
Sex preselection
How sperm commence movement and their isolation for in vitro fertilization and sex selection (Shettles). 1990;163:270 (Letter)
Sex steroids; *see* **Sex hormones**
Sexually transmitted diseases
Bacterial vaginosis: diagnostic and pathogenetic findings during topical clindamycin therapy (Livengood et al). 1990;163:515-20
A follow-up study of methods of contraception, sexual activity, and rates of trichomoniasis, candidiasis, and bacterial vaginosis (Barbone et al). 1990;163:510-4
Pregnancy outcomes among mothers infected with human immunodeficiency virus and uninfected control subjects (Minkoff et al). 1990;163:1598-604
Sexually transmitted diseases and human immunodeficiency virus infection among women with pelvic inflammatory disease (Hoegsberg et al). 1990;163:1135-9
Shirodkar operation; *see* **Cervical incompetence**
Shock
Successful treatment of postpartum shock caused by amniotic fluid embolism with cardiopulmonary bypass and pulmonary artery thromboembolectomy (Esposito et al). 1990;163:572-4
Shoulder dystocia; *see* **Dystocia**
Sickle cell disease; *see* **Anemia, sickle cell**
Sleep, REM
Fetal eye movement assessed with real-time ultrasonography: Are there rapid and slow eye movements? (Horimoto et al). 1990;163:1480-4
Smoking
Risk factors for preterm premature rupture of fetal membranes: a multicenter case-control study (Harger et al). 1990;163:130-7
Short-term effects of smoking on the pharmacokinetic profiles of micronized estradiol in postmenopausal women (Cassidenti et al). 1990;163:1953-60
Smoking and the antioxidant ascorbic acid: plasma, leukocyte, and cervicovaginal cell concentrations in normal healthy women (Basu et al). 1990;163:1948-52
Smooth muscle; *see* **Muscle, smooth**
Society of Perinatal Obstetricians
Transactions of the tenth annual meeting of the Society of Perinatal Obstetricians. 1990;163:715-999
Sodium
Intracellular sodium levels in pregnant women with hypertension (Goodlin) (Letter); (Sowers and Zemel) (Reply). 1990;163:261-2
Sodium nitroprusside; *see* **Nitroprusside**
South Atlantic Association of Obstetricians and Gynecologists
Retrospection and prospection (McLeod). 1990;163:1000-6 (Pres. address)
Transactions of the fifty-second annual meeting of the South Atlantic Association of Obstetricians and Gynecologists. 1990;163:1000-88
Sperm immobilizing agents
A comparison of sperm antibody assays (Daru and Mathur). 1990;163:1622-9
Sperm motility
How sperm commence movement and their isolation for in vitro fertilization and sex selection (Shettles). 1990;163:270 (Letter)
Sperm-ovum interactions, animal
In vitro effect of RU 486 on sperm-egg interaction in mice (Juneja and Dodson). 1990;163:216-21
Spermatocidal agents
A conceptual thought (Pearse). 1990;163:1098 (Letter)
A follow-up study of methods of contraception, sexual activity, and rates of trichomoniasis, candidiasis, and bacterial vaginosis (Barbone et al). 1990;163:510-4
Spermatozoa
Antisperm antibodies in women undergoing intrauterine insemination (Goldberg et al). 1990;163:65-8
A comparison of sperm antibody assays (Daru and Mathur). 1990;163:1622-9
Lectins and heparin-binding features of human spermatozoa as analyzed by flow cytometry (Vasquez et al). 1990;163:2006-12
Lymphocyte proliferative response to fertilization antigen in patients with antisperm antibodies (Naz et al). 1990;163:610-3
Spina bifida
The effect of adjusting maternal serum α-fetoprotein levels for maternal weight in pregnancies with fetal open spina bifida (Johnson et al). 1990;163:9-11
Sprague-Dawley rats; *see* **Rats, inbred strains**
Stains and staining
Comparison of a rapid enzyme-linked immunosorbent assay test and the Gram stain for detection of group B streptococcus in high-risk antepartum patients (Towers et al). 1990;163:965-7
Gram stain results from amniocentesis in patients with preterm permature rupture of membranes—comparison of maternal and fetal characteristics (Asrat et al). 1990;163:887-9
Stamey procedure; *see* **Suspensions**
Statistical analysis; *see* **Factor analysis, statistical**
Sterilization, tubal
Necrotizing fasciitis of the total abdominal wall after sterilization by partial salpingectomy (Cederna et al). 1990;163:138-9
Steroids
Neuromodulatory regulation of gonadotropin-releasing hormone pulsatile discharge in women (Jaffe et al). 1990;163:1727-31 (Supplement)
Steroids, sex; *see* **Contraceptives, oral**
Stillbirth; *see* **Fetal death**
Streptococcus agalactiae
Comparison of a rapid enzyme-linked immunosorbent assay test and the Gram stain for detection of group B streptococcus in high-risk antepartum patients (Towers et al). 1990;163:965-7

Cost-effectiveness of intrapartum screening and treatment for maternal group B streptococci colonization (Strickland et al). 1990;163:4-8 (Clin. opinion)
Perinatal mortality in Victoria, Australia: role of group B streptococcus (Fliegner and Garland). 1990;163:1609-11
Postpartum osteomyelitis caused by group B streptococcus (Berkowitz and McCaffrey). 1990;163:1200-1
Risk factors for perinatal group B streptococcal disease after amniotic fluid colonization (Silver et al). 1990;163:19-25

Stress incontinence, urinary; *see* **Urinary incontinence, stress**

Stroke; *see* **Cerebrovascular disorders**

Stroma ovarii, pathology
Specific binding sites for insulin-like growth factor I in the ovarian stroma of women with polycystic ovarian disease and stromal hyperthecosis (Nagamani and Stuart). 1990;163:1992-7

Stromal hyperthecosis; *see* **Stroma ovarii, pathology**

Stuck twins; *see* **Twins**

Subcutaneous hormone implants; *see* **Estrogen replacement therapy**

Substance abuse
Lack of specific placental abnormality associated with cocaine use (Gilbert et al). 1990;163:998-9
The perinatal impact of cocaine, amphetamine, and opiate use detected by universal intrapartum screening (Gillogley et al). 1990;163:1535-42
Prevalence of use of cocaine and other substances in an obstetric population (Matera et al). 1990;163:797-801
Progesterone increases cardiovascular toxicity to cocaine in nonpregnant ewes (Plessinger and Woods). 1990;163:1659-64

Sulfite oxidases
Antenatal diagnosis of molybdenum cofactor deficiency (George et al). 1990;163:1203-4

Supreme court decisions; *see* **Jurisprudence**

Surface-active agents
Prevalence and etiology of respiratory distress in infants of diabetic mothers: predictive value of fetal lung maturation tests (Kjos et al). 1990;163:898-903

Surface glycoproteins; *see* **Membrane glycoproteins**

Surfactants; *see* **Surface-active agents**

Surgery, operative
Adhesion formation after ovarian wound repair in New Zealand white rabbits: a comparison of ovarian microsurgical closure with ovarian nonclosure (Wiskind et al). 1990;163:1674-8
Continuous or interrupted fascial closure: a prospective evaluation of No.1 Maxon suture in 402 gynecologic procedures (Orr et al). 1990;163:1485-9
A convenient method to identify prior surgical procedures (Letterie et al). 1990;163:1100 (Letter)
The Maylard incision in gynecologic cancer (Helmkamp and Krebs). 1990;163:1554-7
Surgical staples in cesarean section: a randomized controlled trial (Villeneuve et al). 1990;163:1641-6

Surgical instruments
Fluid cooling of artificial sapphire tips of laser (Loffer) (Letter); (Baggish) (Reply). 1990;163:681
Preventing cervical conization by achieving satisfactory colposcopy with hygroscopic cervical dilators (Stern et al). 1990;163:176-7
Sapphire probes in obstetric laser surgery (Corson) (Letter); (Baggish and Daniell) (Reply). 1990;163:246-7

Surgical menopause, animal; *see* **Menopause, premature, animal**

Surgical staplers
Surgical staples in cesarean section: a randomized controlled trial (Villeneuve et al). 1990;163:1641-6

Surgical techniques and equipment; *see* **Surgery, operative**

Surrogate mothers
Surrogate parenting contracts (Wettstein) (Letter); (La Puma et al) (Reply). 1990;163:679-80

Survival
Mortality rates ignore population segment (Harkavy) (Letter); (Resnick and Ariet) (Reply). 1990;163:269-70
Perinatal survival with expectant management of midtrimester rupture of membranes (Major and Kitzmiller). 1990;163:838-44
Prolongation of pregnancy and survival of second twin (Goodlin) (Letter); (Feichtinger) (Reply). 1990;163:270-1
Survival and outcome of infants weighing <800 grams at birth (Lipper et al). 1990;163:146-50
Survival rates of monoamniotic twins do not decrease after 30 weeks' gestation (Carr et al). 1990;163:719-22

Suspensions
Retropubic long-needle suspension procedures for stress urinary incontinence (Varner). 1990;163:551-7

Sutures
Continuous or interrupted fascial closure: a prospective evaluation of No.1 Maxon suture in 402 gynecologic procedures (Orr et al). 1990;163:1485-9

Sympathomimetics
Role of the endothelium in adrenergic responses of mesenteric artery rings of pregnant rats (Parent et al). 1990;163:229-34

Symphysiotomy
Safe motherhood: Cesarean section or symphysiotomy? (van Roosmalen). 1990;163:1-4 (Clin. opinion)

Syphilis
False-negative syphilis screening: the prozone phenomenon, nonimmune hydrops, and diagnosis of syphilis during pregnancy (Berkowitz et al). 1990;163:975-7
The relationship of cocaine use to syphilis and human immunodeficiency virus infections among inner city parturient women (Minkoff et al). 1990;163:521-6

T

T-ACE questions; *see* **Questionnaires**

T-lymphocytes
Soluble factors produced by isolated first-trimester chorionic villi directly inhibit proliferation of T cells (Silver et al). 1990;163:1914-9

TAG 72; *see* **Antigens, tumor-associated, carbohydrate**

Telemetry
Blood pressure measured telemetrically from home throughout pregnancy (Mooney et al). 1990;163:30-6

Teratogens; *see also* **Carcinogens**
Correlations between antepartum maternal metabolism and newborn behavior (Rizzo et al). 1990;163:1458-64
Embryofetal effects of pentamidine isethionate administered to pregnant Sprague-Dawley rats (Harstad et al). 1990;163:912-6
Perception of teratogenic risk by pregnant women exposed to diagnostic radiation during pregnancy (Mastroiacovo et al) (Letter); (Koren) (Reply). 1990;163:695-6
Pregnancy in a patient with treated Wilson's disease: a case report (Dupont et al). 1990;163:1527-8

Teratoma
Survival in a fetus with sacrococcygeal teratoma and hydrops (Nakayama). 1990;163:682 (Letter)
Terbutaline
Diabetic ketoacidosis and insulin resistance with subcutaneous terbutaline infusion: a case report (Tibaldi et al). 1990;163:509-10
Effect of tocolytic agents on fetal umbilical velocimetry (Wright et al). 1990;163:748-50
A prospective randomized comparison of oral terbutaline and magnesium oxide for the maintenance of tocolysis (Ridgway et al). 1990;163:879-82
Testosterone
Autogenic masculinization (Punch and Ansbacher). 1990;163:114-6
Suppression of serum insulin level by diazoxide does not alter serum testosterone of sex hormone–binding globulin levels in healthy, nonobese women (Nestler et al). 1990;163:1243-6
Thorax
Prenatal diagnosis of a chest wall mass with ultrasonography and Doppler velocimetry: a case report (Smith et al). 1990;163:567-9
Thrombin
Clinical aspects of the relationship between oral contraceptives and abnormalities of the hemostatic system: relation to the development of cardiovascular disease (Kelleher). 1990;163:392-5 (Supplement)
Thrombocytopenia
Continuing controversy in alloimmune thrombocytopenia: fetal hyperimmunoglobulinemia fails to prevent thrombocytopenia (Nicolini et al). 1990;163:1144-6
Cordocentesis and immune thrombocytopenia—continued (Weiner). 1990;163:1371-2 (Letter)
The natural history of thrombocytopenia associated with preeclampsia (Katz et al). 1990;163:1142-3
Responsibility expands to extended family members (Saving et al). 1990;163:1369-70 (Letter)
Thrombocytopenia purpura; *see* **Purpura, thrombocytopenic**
Thromboembolectomy; *see* **Thrombosis**
Thrombosis
Disorders of the hemostatic system and the risk of the development of thrombotic and cardiovascular diseases: limitations of laboratory diagnosis (Kluft). 1990;163:305-12 (Supplement)
Interrelations between carbohydrates, lipids, and the hemostatic system in relation to the risk of thrombotic and cardiovascular disease (Juhan-Vague and Vague). 1990;163:313-5 (Supplement)
Oral contraception in disease states (Breckwoldt et al). 1990;163:2213-6 (Symposium)
Successful treatment of postpartum shock caused by amniotic fluid embolism with cardiopulmonary bypass and pulmonary artery thromboembolectomy (Esposito et al). 1990;163:572-4
Ultrasonographic diagnosis of a large placental intervillous thrombosis associated with elevated maternal serum α-fetoprotein level (Jauniaux et al). 1990;163:1558-60
Thromboxane
Placental thromboxane and prostacyclin production in an ovine diabetic model (Dickinson et al). 1990;163:1831-5
Thromboxane A_2, analog
Effects of magnesium and isradipine on contractile activation induced by the thromboxane A_2 analog U46619 in human uteroplacental arteries in term pregnancy (Skajaa et al). 1990;163:1323-33
Thromboxane synthetase, antagonists and inhibitors
Fetal and maternal response to intravenous infusion of a thromboxane synthetase inhibitor (Cardin et al). 1990;163:1345-9
Thyrotropin releasing hormone
Dose response of thyrotropin-releasing hormone on pulmonary maturation in corticosteroid-treated preterm rabbits (Tabor et al). 1990;163:669-76
Thyroxine
Screening infertile women for subclinical hypothyroidism (Strickland et al) (Letter); (Wilansky and Greisman) (Reply). 1990;163:262-3
Tissue culture
Epithelial cells from normal human endometrium express a tumor-associated glycoprotein (TAG-72) epitope in vitro (Osteen et al). 1990;163:479-84
Tissue donors
Anencephalics as organ donors (Van Assche). 1990;163:599-600
Tissue-type plasminogen activator; *see* **Plasminogen activator, tissue-type**
Tocolysis
Adjusting the loading dose of magnesium sulfate for tocolysis (Wright et al). 1990;163:889-92
Awaiting cervical change for the diagnosis of preterm labor does not compromise the efficacy of ritodrine tocolysis (Utter et al). 1990;163:882-6
A comparison of tocolysis with nifedipine or ritodrine: analysis of efficacy and maternal, fetal, and neonatal outcome (Ferguson et al). 1990;163:105-11
Effects of ritodrine tocolysis on cardiac isozymes and electrocardiography (Hendricks and Katz) (Letter); (Hadi and Albazzaz) (Reply). 1990;163:699-701
A prospective randomized comparison of oral terbutaline and magnesium oxide for the maintenance of tocolysis (Ridgway et al). 1990;163:879-82
Uterine hyperstimulation after low-dose prostaglandin E_2 therapy: tocolytic treatment in 181 cases (Egarter et al). 1990;163:794-6
Tocolytic agents
A comparison of tocolysis with nifedipine or ritodrine: analysis of efficacy and maternal, fetal, and neonatal outcome (Ferguson et al). 1990;163:105-11
Effect of tocolytic agents on fetal umbilical velocimetry (Wright et al). 1990;163:748-50
Effects of ritodrine tocolysis on cardiac isozymes and electrocardiography (Hendricks and Katz) (Letter); (Hadi and Albazzaz) (Reply). 1990;163:699-701
Inhibition of spontaneous uterine contractions during the last trimester in pregnant baboons by an oxytocin antagonist (Wilson et al). 1990;163:1875-82
A new tocolytic agent: development of an oxytocin antagonist for inhibiting uterine contractions (Wilson et al). 1990;163:195-202
Tomography, x-ray computed
Prenatal diagnosis of fetal intracranial calcifications (Koga et al). 1990;163:1543-5
Toxicology
Prevalence of use of cocaine and other substances in an obstetric population (Matera et al). 1990;163:797-801
Toxoplasmosis, congenital
Detection of congenital toxoplasmosis by chorionic villus

sampling and early amniocentesis (Foulon et al). 1990;163:1511-3

Transabdominal ultrasonography; *see* **Ultrasonic diagnosis**

Transactions

Transactions of the fifty-second annual meeting of the South Atlantic Association of Obstetricians and Gynecologists. 1990;163:1000-88

Transactions of the tenth annual meeting of the Society of Perinatal Obstetricians. 1990;163:715-999

Transcervical chorionic villus sampling; *see* **Chorionic villi sampling**

Transcortin

Protein binding of active ingredients and comparison of serum ethinyl estradiol sex hormone–binding globulin, corticosteroid-binding globulin, and cortisol levels in women using a combination of gestodene/ethinyl estradiol (Femovan) or a combination of desogestrel/ethinyl estradiol (Marvelon) and single-dose ethinyl estradiol bioequivalence from both oral contraceptives (Hümpel et al). 1990;163:329-33 (Supplement)

Transforming growth factors

Interleukin-1β, human leukocyte antigen DR1, and transforming growth factor-β expression in endometrium, placenta, and placental membranes (Kauma et al). 1990;163:1430-7

Transplacental exposure; *see* **Maternal-fetal exchange**

Transplantation

Anencephalics as organ donors (Van Assche). 1990;163:599-600

Transvaginal ultrasonography; *see* **Ultrasonic diagnosis**

Trial of labor

Reducing cesarean sections at a teaching hospital (Sanchez-Ramos et al). 1990;163:1081-8

Trichomonas vaginitis

Bacterial vaginosis and trichomoniasis vaginitis are risk factors for cuff cellulitis after abdominal hysterectomy (Soper et al). 1990;163:1016-23

A follow-up study of methods of contraception, sexual activity, and rates of trichomoniasis, candidiasis, and bacterial vaginosis (Barbone et al). 1990;163:510-4

Triplets

Credit neonatal or obstetric care? (Weissman and Jakobi) (Letter); (Milligan) (Reply). 1990;163:1716

Trisomy

The association of single umbilical artery with cytogenetically abnormal pregnancies (Saller et al). 1990;163:922-5

Growth of linear parameters in trisomy 18 fetuses (Droste et al). 1990;163:158-61

Maternal serum Down syndrome screening: free β-protein is a more effective marker than human chorionic gonadotropin (Macri et al). 1990;163:1248-53

Screening for trisomy 21 with ultrasonographic determination of biparietal diameter/femur length ratio (Marquette et al). 1990;163:1604-5

Ultrasonographic detection of the second-trimester fetus with trisomy 18 and trisomy 21 (Ginsberg et al). 1990;163:1186-90

Trophoblast

HBcAg identification in the placental cytotypes of symptom-free HBsAg-carrier mothers: a study with the immunoperoxidase method (Lucifora et al). 1990;163:235-9

Inhibition of aromatase activity by 8-bromo-cyclic adenosine monophosphate in cultured first-trimester human trophoblast (Rodway et al). 1990;163:1546-51

Soluble factors produced by isolated first-trimester chorionic villi directly inhibit proliferation of T cells (Silver et al). 1990;163:1914-9

Trophoblastic tumor

Prediction of residual trophoblastic tissue in first-trimester abortions: the role of transvaginal Doppler ultrasonography (Reuwen). 1990;163:2024-5 (Letter)

Tuberculosis, female genital

An abdominal pregnancy 10 years after treatment for pelvic tuberculosis (Durukan et al). 1990;163:594-5

Tubocurarine

Differential sensitivities of fetal muscle groups to *d*-tubocurarine (Szeto and Hinman). 1990;163:202-9

Tumor antigens; *see* **Antigens, neoplasm**

Tumor-associated glycoproteins; *see* **Membrane glycoproteins**

Tumor necrosis factor

Proliferative and antiproliferative effects of interferon-γ and tumor necrosis factor-α on cell lines derived from cervical and ovarian malignancies (Mutch et al). 1990;163:1920-4

Serum levels of interleukin-2 and tumor necrosis factor α in women with recurrent abortion (Mallmann et al). 1990;163:1367 (Letter)

Tumorigenicity tests; *see* **Carcinogens**

Turner's syndrome

Correlation of the testicular determinant factor sequence zinc finger Y with varying gonadal phenotypes in a series of 13 subjects with gonadal dysgenesis because of Y aneuploidy (Tho et al). 1990;163:1968-75

Twin-to-twin transfusion; *see* **Fetofetal transfusion**

Twin transfusion; *see* **Fetofetal transfusion**

Twins

Fetal Doppler velocimetry in twins (Degani) (Letter); (Divon) (Reply). 1990;163:1100-1

Infection and labor. VI. Prevalence, microbiology, and clinical significance of intraamniotic infection in twin gestations with preterm labor (Romero et al). 1990;163:757-61

Prognosis for twins with birth weight <1500 gm: the impact of cesarean section in relation to fetal presentation (Rydhström). 1990;163:528-33

Prolongation of pregnancy and survival of second twin (Goodlin) (Letter); (Feichtinger) (Reply). 1990;163:270-1

The stuck twin phenomenon: Ultrasonographic findings, pregnancy outcome, and management with serial amniocenteses (Mahony et al). 1990;163:1513-22

Twin-twin transfusion syndrome (Urig et al). 1990;163:1522-6

Twins, monozygotic

Perinatal outcome of forty-nine pregnancies complicated by acardiac twinning (Moore et al). 1990;163:907-12

Survival rates of monoamniotic twins do not decrease after 30 weeks' gestation (Carr et al). 1990;163:719-22

U

Ulcer, vulvar; *see* **Vulvar diseases**

Ultrasonic diagnosis

Accuracy of apical four-chamber view as screen for congenital heart disease (Stephens). 1990;163:249-50 (Letter)

Appropriate screening tests (Nagey) (Letter); (Chervenak et al) (Reply). 1990;163:688-9

Assessment of cerebral hemodynamics in pregnant women by internal carotid artery pulsed Doppler velocimetry (Ikeda and Mori). 1990;163:494-8

Blood flow velocity and pulsatile diameter changes in the

Ultrasonic diagnosis—cont'd
fetal descending aorta: a longitudinal study (Stale et al). 1990;163:26-9
Color flow Doppler—a useful instrument in the diagnosis of vasa previa (Harding et al). 1990;163:1566-8
The diagnostic values of concurrent nonstress testing, amniotic fluid measurement, and Doppler velocimetry in screening a general high-risk population (Devoe et al). 1990;163:1040-8
Direct ultrasonographic measurement of fetal lung length in normal pregnancies and pregnancies complicated by prolonged rupture of membranes (Roberts and Mitchell). 1990;163:1560-6
Does the umbilical artery systolic/diastolic ratio reflect flow or acidosis? (Copel et al). 1990;163:751-6
Ductus arteriosus flow velocity modulation by fetal breathing movements as a measure of fetal lung development (van Eyck et al). 1990;163:558-66
The effect of nifedipine therapy on fetal and placental Doppler waveforms in preeclampsia remote from term (Moretti et al). 1990;163:1844-8
Effects of intravascular fetal blood transfusion on fetal intracardiac Doppler velocity waveforms (Rizzo et al). 1990;163:1231-8
Endometrial assessment by vaginal ultrasonography before endometrial sampling in patients with postmenopausal bleeding (Goldstein et al). 1990;163:119-23
Ethics and routine ultrasonography in pregnancy (Ewigman et al) (Letter); (Chervenak et al) (Reply). 1990;163:256-8
Fetal Doppler velocimetry in twins (Degani) (Letter); (Divon) (Reply). 1990;163:1100-1
Fetal eye movement assessed with real-time ultrasonography: Are there rapid and slow eye movements? (Horimoto et al). 1990;163:1480-4
Fetal umbilical artery Doppler response to graded maternal aerobic exercise and subsequent maternal mean arterial blood pressure: predictive value for pregnancy-induced hypertension (Hume et al). 1990;163:826-9
Human fetal foramen ovale flow velocity waveforms relative to behavioral states in normal term pregnancy (van Eyck et al). 1990;163:1239-42
Hypoxic acidemia, hyperviscosity, and maternal hypertension do not affect the umbilical arterial velocity waveform in fetal sheep (Morrow et al). 1990;163:1313-20
In utero detection of cardiac failure from an aneurysm of the vein of Galen (Jeanty et al). 1990;163:50-1
Infants of diabetic mothers with accelerated fetal growth by ultrasonography: Are they all alike? (Keller et al). 1990;163:893-7
Observations on the cause of oligohydramnios in prolonged pregnancy (Trimmer et al). 1990;163:1900-3
Prediction of residual trophoblastic tissue in first-trimester abortions: the role of transvaginal Doppler ultrasonography (Reuwen). 1990;163:2024-5 (Letter)
Prediction of risk for preterm delivery by ultrasonographic measurement of cervical length (Andersen et al). 1990;163:859-67
Prenatal diagnosis of a chest wall mass with ultrasonography and Doppler velocimetry: a case report (Smith et al). 1990;163:567-9
Relationship between the ovine fetal umbilical artery blood flow waveform and umbilical vascular resistance (Irion and Clark). 1990;163:222-9
Reliability of ultrasonographic formulary in the prediction of fetal weight and survival of very-low-birth-weight infants (Mills et al). 1990;163:1568-74
Screening for trisomy 21 with ultrasonographic determination of biparietal diameter/femur length ratio (Marquette et al). 1990;163:1604-5
Second-trimester ultrasonography: determinants of visualization of fetal anatomic structures (Catanzarite and Quirk). 1990;163:1191-5
Spontaneous resolution of a nuchal fetal cystic hygroma diagnosed early in the second trimester of pregnancy (Meizner et al) (Letter); (Bronshstein and Blumenfeld) (Reply). 1990;163:267-9
Superiority of the four-quadrant sum over the single-deepest-pocket technique in ultrasonographic identification of abnormal amniotic fluid volumes (Moore). 1990;163:762-7
Transabdominal and transvaginal ultrasonography in the diagnosis of ectopic pregnancy: a comparative study (Kivikoski et al). 1990;163:123-8
Transvaginal ultrasonographic detection of congenital anomalies in the first trimester (Cullen et al). 1990;163:466-76
Ultrasonographic assessment of intestinal damage in fetuses with gastroschisis: Is it of clinical value? (Lenke et al). 1990;163:995-8
Ultrasonographic assessment of placental abnormalities (Jauniaux and Campbell). 1990;163:1650-8
Ultrasonographic dating of very early pregnancy (Cadkin and McAlpin-Cadkin). 1990;163:1103 (Letter)
Ultrasonographic detection of the second-trimester fetus with trisomy 18 and trisomy 21 (Ginsberg et al). 1990;163:1186-90
Ultrasonographic diagnosis of a large placental intervillous thrombosis associated with elevated maternal serum α-fetoprotein level (Jauniaux et al). 1990;163:1558-60
Ultrasonographic evaluation of uteroplacental blood flow patterns of abnormally located and adherent placentas (Guy et al). 1990;163:723-7
Ultrasonographic fetal weight estimation by an integrated computer-assisted system: Can each laboratory improve its accuracy? (Thompson et al). 1990;163:986-95
Ultrasonographic guidance for central venous access (Greenspoon) (Letter); (Lee) (Reply). 1990;163:252
Ultrasonography's role in detection of intrauterine synechiae (Stephens) (Letter); (Valle and Sciarra) (Reply). 1990;163:1106-7
Vaginal probe ultrasonography and ectopic pregnancy (Goldstein) (Letter); (Stiller) (Reply). 1990;163:1099-100
Variation and correlation in human fetal umbilical Doppler velocities with fetal breathing: evidence of the cardiac-placental connection (Indik and Reed). 1990;163:1792-6

Umbilical arteries
The association of single umbilical artery with cytogenetically abnormal pregnancies (Saller et al). 1990;163:922-5
Comparison of umbilical artery pH and 5-minute Apgar score in the low-birth-weight and very-low-birth-weight infant (Stark et al). 1990;163:818-23
Effect of tocolytic agents on fetal umbilical velocimetry (Wright et al). 1990;163:748-50
Fetal umbilical artery Doppler response to graded maternal aerobic exercise and subsequent maternal mean arterial blood pressure: predictive value for pregnancy-induced hypertension (Hume et al). 1990;163:826-9
Sources of variability in umbilical artery systolic/diastolic ratios: implications of Poiseuille equation (Wright and Ridgway). 1990;163:1788-91
Variation and correlation in human fetal umbilical Doppler

velocities with fetal breathing: evidence of the cardiac-placental connection (Indik and Reed). 1990;163:1792-6

Umbilical arteries, animal

Does the umbilical artery systolic/diastolic ratio reflect flow or acidosis? (Copel et al). 1990;163:751-6

Hypoxic acidemia, hyperviscosity, and maternal hypertension do not affect the umbilical arterial velocity waveform in fetal sheep (Morrow et al). 1990;163:1313-20

Relationship between the ovine fetal umbilical artery blood flow waveform and umbilical vascular resistance (Irion and Clark). 1990;163:222-9

Umbilical cord

A comparison of the effect of epidural, general, and no anesthesia on funic acid-base values by stage of labor and type of delivery (Shyken et al). 1990;163:802-7

Effects of magnesium and isradipine on contractile activation induced by the thromboxane A_2 analog U46619 in human uteroplacental arteries in term pregnancy (Skajaa et al). 1990;163:1323-33

Sources of variability in umbilical artery systolic/diastolic ratios: implications of Poiseuille equation (Wright and Ridgway). 1990;163:1788-91

Umbilical veins

Acute fetal hemodynamic alterations after intrauterine transfusion for treatment of severe red cell alloimmunization (Moise et al). 1990;163:776-84

Umbilical velocimetry; *see* **Flowmeters**

Universal screening; *see* **Mass screening**

Ureaplasma

Cervicovaginal microflora and pregnancy outcome: results of a double-blind, placebo-controlled trial of erythromycin treatment (McGregor et al). 1990;163:1580-91

Urinary calcium; *see* **Calcium**

Urinary incontinence

The effect of large uterine fibroids on urinary bladder function symptoms (Langer et al). 1990;163:1139-41

Urinary incontinence, stress

The effect of large uterine fibroids on urinary bladder function symptoms (Langer et al). 1990;163:1139-41

Retropubic long-needle suspension procedures for stress urinary incontinence (Varner). 1990;163:551-7

Suprapubic or vaginal procedure (Cabrera et al) (Letter); (Bergman et al) (Reply). 1990;163:2025-6

Uterine catheterization

Alteration of 24-hour rhythms in myometrial activity in the chronically catheterized pregnant rhesus monkey after a 6-hour shift in the light-dark cycle (Figueroa et al). 1990;163:648-54

Uterine contraction

The effect of amnioinfusion on uterine pressure and activity: a preliminary report (Posner et al). 1990;163:813-8

Gestational changes in mechanical properties of skinned muscle tissues of human myometrium (Izumi et al). 1990;163:638-47

A new tocolytic agent: development of an oxytocin antagonist for inhibiting uterine contractions (Wilson et al). 1990;163:195-202

Studies of the spontaneous motility and the effect of histamine on isolated myometrial strips of the nonpregnant human uterus: the influence of various uterine abnormalities (Martinez-Mir et al). 1990;163:189-95

Uterine contraction, animal

Inhibition of spontaneous uterine contractions during the last trimester in pregnant baboons by an oxytocin antagonist (Wilson et al). 1990;163:1875-82

A mechanism leading to reduced lung expansion and lung hypoplasia in fetal sheep during oligohydramnios (Harding et al). 1990;163:1904-13

Vasodilatory effects of nifedipine, methoxyverapamil, and sodium nitroprusside on contractile responses of the ewe uterine artery at term pregnancy (Isla and Dyer). 1990;163:1337-44

Uterine hemorrhage

Oral contraceptives in risk groups: Exclusion or monitoring? (Guillebaud). 1990;163:443-6 (Supplement)

Uterine hyperstimulation; *see* **Labor complications**

Uterine neoplasms

The effect of large uterine fibroids on urinary bladder function symptoms (Langer et al). 1990;163:1139-41

Efficacy and safety considerations in women with uterine leiomyomas treated with gonadotropin-releasing hormone agonists: the estrogen threshold hypothesis (Friedman et al). 1990;163:1114-9 (Clin. opinion)

Experience with the EndoPap device for the cytologic detection of uterine cancer and its precursors: a comparison of the EndoPap with fractional curettage or hysterectomy (LaPolla et al). 1990;163:1055-60

Preoperative evaluation of serum CA 125, TAG 72, and CA 15-3 in patients with endometrial carcinoma (Soper et al). 1990;163:1204-9

Uterine prolapse

A vesicovaginal fistula and intravesical foreign body: a rare case of the neglected pessary (Goldstein et al). 1990;163:589-91

Uterine rupture

Catastrophic complications of previous cesarean section (Chazotte and Cohen). 1990;163:738-42

Intrapartum uterine rupture and inflammatory bowel disease (Peterson and Braak). 1990;163:1247-8

Rupture of unscarred uterus in primigravid woman in association with cocaine abuse (Gonsoulin et al). 1990;163:526-7

Uteroplacental blood flow; *see* **Placenta**

Uterus

The effect of amnioinfusion on uterine pressure and activity: a preliminary report (Posner et al). 1990;163:813-8

Experience with the EndoPap device for the cytologic detection of uterine cancer and its precursors: a comparison of the EndoPap with fractional curettage or hysterectomy (LaPolla et al). 1990;163:1055-60

Laparoscopic ventrosuspensions (Yoong). 1990;163:1151-3

Modified laparoscopy for monitoring transcervical surgery (Lin and Iwata). 1990;163:243-4 (Letter)

Studies of the spontaneous motility and the effect of histamine on isolated myometrial strips of the nonpregnant human uterus: the influence of various uterine abnormalities (Martinez-Mir et al). 1990;163:189-95

Uterine artery estrogen receptors in the nonpregnant and pregnant guinea pig (Leiberman et al). 1990;163:1685-8

Uterus, animal

Vasodilatory effects of nifedipine, methoxyverapamil, and sodium nitroprusside on contractile responses of the ewe uterine artery at term pregnancy (Isla and Dyer). 1990;163:1337-44

V

Vacuum extraction

Risk factors for third-degree and fourth-degree perineal lacerations in forceps and vacuum deliveries (Combs et al). 1990;163:100-4

Vagina
Endometrial assessment by vaginal ultrasonography before endometrial sampling in patients with postmenopausal bleeding (Goldstein et al). 1990;163:119-23
Vaginal diseases
Bacterial vaginosis: diagnostic and pathogenetic findings during topical clindamycin therapy (Livengood et al). 1990;163:515-20
A follow-up study of methods of contraception, sexual activity, and rates of trichomoniasis, candidiasis, and bacterial vaginosis (Barbone et al). 1990;163:510-4
Vaginitis
Bacterial vaginosis: diagnostic and pathogenetic findings during topical clindamycin therapy (Livengood et al). 1990;163:515-20
Bacterial vaginosis and trichomoniasis vaginitis are risk factors for cuff cellulitis after abdominal hysterectomy (Soper et al). 1990;163:1016-23
A follow-up study of methods of contraception, sexual activity, and rates of trichomoniasis, candidiasis, and bacterial vaginosis (Barbone et al). 1990;163:510-4
Valve prosthesis; *see* **Heart valve prosthesis**
Vanable decelerations; *see* **Heart rate, fetal**
Vancomycin, adverse effects
Toxicity of vancomycin given during pregnancy (Gouyon and Petion) (Letter); (Reyes and Ostrea) (Reply). 1990;163:1375-6
Varicella-zoster virus
Extensive vulvar and vaginal varicella necessitating abdominal delivery (Sites et al). 1990;163:1630-1
Vasa previa; *see* **Placenta praevia**
Vascular access ports; *see* **Catheters, indwelling**
Vascular resistance
Response of placental vasculature to high glucose levels in the isolated human placental cotyledon (Roth et al). 1990;163:1828-30
Vascular resistance, animal
Maternal and uteroplacental hemodynamic effects of chronic captopril in the hypertensive, term-pregnant rat (Mabie et al). 1990;163:1861-7
Relationship between the ovine fetal umbilical artery blood flow waveform and umbilical vascular resistance (Irion and Clark). 1990;163:222-9
Vasopressin; *see* **Argipressin**
Oxytocin and vasopressin binding sites in human and bovine ovaries (Fuchs et al). 1990;163:1961-7
Vein of Galen; *see* **Cerebral veins**
Velocimetry; *see* **Flowmeters**
Venous access; *see* **Catheters, indwelling**
Verapamil
Vasodilatory effects of nifedipine, methoxyverapamil, and sodium nitroprusside on contractile responses of the ewe uterine artery at term pregnancy (Isla and Dyer). 1990;163:1337-44
Vesicovaginal fistula
A vesicovaginal fistula and intravesical foreign body: a rare case of the neglected pessary (Goldstein et al). 1990;163:589-91
Viability of fetus; *see* **Fetal viability**
Vibroacoustic stimulation; *see* **Acoustic stimulation**
Vision disorders
Neuroophthalmologic effects of intravenous magnesium sulfate (Digre et al). 1990;163:1848-52
Vitamin C; *see* **Ascorbic acid**
Vitamin E
Vitamin E levels in premenstrual syndrome (Chuong et al). 1990;163:1591-5
von Hippel-Lindau disease; *see* **Hippel-Lindau disease**
von Willebrand factor
Hemostasis profile in women taking low-dose oral contraceptives (David et al). 1990;163:420-3 (Supplement)
Vulvar diseases
Autogenic masculinization (Punch and Ansbacher). 1990;163:114-6
Vulvar ulcer of unknown etiology in a human immunodeficiency virus–infected woman: response to treatment with zidovudine (Covino and McCormack). 1990;163:116-8
Vulvar neoplasms
Invasive carcinoma of the vulva (Cavanagh et al). 1990;163:1007-15

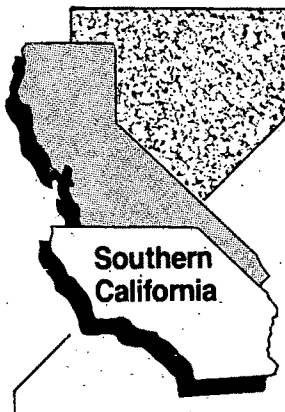
W

Webster vs Reproductive Health Services; *see* **Jurisprudence**
Wilson's disease; *see* **Hepatolenticular degeneration**

X

X chromosome
Cytogenetic uncertainties surrounding the fragile X in Martin-Bell syndrome (Sindwani and Verma). 1990;163:1713-4 (Letter)

Z



Zidovudine
Transplacental transfer of zidovudine in the near-term pregnant baboon (Hankins et al). 1990;163:728-32
Vulvar ulcer of unknown etiology in a human immunodeficiency virus–infected woman: response to treatment with zidovudine (Covino and McCormack). 1990;163:116-8
Zinc
Zinc, preeclampsia, and γ-aminobutyric acid (Brophy). 1990;163:242-3 (Letter)

Outstanding Obstetrics-Gynecology practice opportunity!

Located on Ohio's North coast with the best of four seasons in a city with excellent schools and cultural attractions.

600+ bed tertiary care medical center. Comprehensive services provided in a growing OB/GYN department. Excellent clinical and diagnostic facilities. Very competitive financial package available for qualified BE/BC physician.

Interested individuals may send CV in confidence to:
Ellen F. Yunker
Manager, Physician Recruitment,
St. Vincent Medical Center
2213 Cherry Street
Toledo, OH 43608-2691
or call (419) 321-4462

Join The Partnership of Choice

Southern California Permanente Medical Group (SCPMG) is recognized as the nation's largest and most respected physician-managed, multi-specialty medical group.

Our continued growth has created new opportunities for:

OBSTETRICIANS & GYNECOLOGISTS

You'll have a choice of professional environments ranging from a 250-bed community hospital to a major teaching facility in a number of prime Southern California locations. Our active practices require proficiency in modern ultrasound and surgical techniques.

CHIEF OF SERVICE

An excellent opportunity for an experienced OB/GYN practitioner to lead an established and growing practice at our Panorama City Medical Center. You'll be responsible for supervising 20 OB/GYN Physicians, a Perinatologist, 8 Certified Nurse Midwives and 4 Nurse Practitioners. This team of professionals will handle approximately 3000 deliveries per year.

SCPMG provides the freedom, technology and resources to focus on quality patient care and the collaborative support of knowledgeable colleagues. **We also provide a highly competitive salary, paid malpractice and predictable hours.**

KAISER PERMANENTE
Southern California Permanente Medical Group

Partners Practicing Good Medicine

Call or send your CV to:
Irwin P. Goldstein, M.D., Associate Medical Director
SCPMG, Dept. 006
Walnut Center, Pasadena, CA 91188-8013
Or Call: 1-800-541-7946

RESIDENCY IN OBSTETRICS/ GYNECOLOGY

The Department of Obstetrics and Gynecology at Akron City Hospital has an ACGME approved position available at the PGY-2 level beginning immediately. Applicants must have received one year of Obstetrics/Gynecology training in a ACGME approved training program.

Send letter of application and curriculum to:

John Karlen, M.D.
Chairman and Residency Director
Akron City Hospital
525 East Market Street
Akron, Ohio 44309

Akron City Hospital is an equal opportunity affirmative action employer.

OBSTETRICIAN/ GYNECOLOGIST

Large, independent multi-specialty group in Minneapolis-St. Paul metropolitan area seeks additional BC/BE obstetrician/gynecologists to join challenging, established practice spanning the full range of obstetrics and gynecology. Competitive salary and benefit package. Send inquiries and curriculum vitaes to:

Nancy Borgstrom
Administration
Aspen Medical Group
1020 Bandana Boulevard West
St. Paul, MN 55108
(612) 641-7185

Equal Opportunity Employer

Finger Lakes Region Ithaca, New York

Unique opportunity for patient oriented physician in comprehensive OB-GYN service, building on established patient base of 6,000 patients. To include out-patient gynecology, obstetrics, surgery, infertility, and abortions. First call protection from nurse-midwives. Progressive university community (home of Cornell University) offers cultural attractions of a city with the benefits of small town living. Competitive salary, excellent benefits including malpractice. Summer/Fall 1991.

Send CV To: Joyce Leslie, M.D., Planned Parenthood of Tompkins County, 314 W. State St., Ithaca, NY 14850.

Planned Parenthood®
of Tompkins County

PROFESSOR AND DIRECTOR DIVISION OF GYNECOLOGIC ONCOLOGY

A full time faculty position is available for Professor, and Director of the Division of Gynecological Oncology 1 April 1991. Excellent opportunities exist for teaching and research. A new University Hospital opened in November, 1989. The division has an active clinical service in Parkland Memorial Hospital, and is involved in multiple GOG protocols. There is an approved 3-year fellowship program and the first year consists of laboratory research.

Salary and faculty appointment are commensurate with curriculum vitae and experience. Board certification in gynecological oncology required. Direct all inquiries to: David Hemsell, M.D., Chair, Search Committee, Department Obstetrics & Gynecology, University of Texas Southwestern Medical Center at Dallas, 5323 Harry Hines Boulevard, Dallas, TX 75235-9032. An affirmative action/equal opportunity employer.

FULL-TIME FACULTY
OB/GYN GENERALIST

The Department of Obstetrics and Gynecology of the Bowman Gray School of Medicine of Wake Forest University is seeking an additional generalist. The position involves primary responsibility in General Gynecology with teaching and supervision of residents and students in a clinical setting and some private practice. There is opportunity for participation in both clinical and basic research.

The Bowman Gray School of Medicine is located in the Piedmont Triad of North Carolina in an area offering an unusual diversity of cultural and recreational amenities.

Competitive salary, fringe benefit package and academic appointment are offered in accordance with experience. Send CV to:

Eberhard Mueller-Heubach, M.D.
Professor and Chairman
Department of Obstetrics and Gynecology
Bowman Gray School of Medicine
Wake Forest University
300 South Hawthorne Road
Winston-Salem, NC 27103

The Wake Forest University is an equal opportunity affirmative action employer. Women and minorities are encouraged to apply.

BRIDGEPORT HOSPITAL
Bridgeport, Connecticut
DEPARTMENT OF OB/GYN
is seeking a full time
3rd PERINATOLOGIST

The department performs approximately 3000 deliveries/ year, with an additional 3000 deliveries performed in neighboring Level I hospitals. There is an accreditated residency program in Obstetrics and Gynecology, along with a Level III Intensive Care Nursery. The section provides high risk obstetrical consultation, obstetrical imaging, genetic counseling. There is a close affiliation with the Yale Department of OB/GYN and abundant opportunities for clinical research.

We are looking for a BC/BE individual with an interest in clinical perinatology and a strong background in perinatal genetics to complement our existing services. The salary and benefits offered by the institution are extremely competitive and Fairfield County is an attractive place to live and raise a family.

Interested candidates should send their CV to:

Robert J. Stiller, M.D.
Director, Maternal-Fetal Medicine
Bridgeport Hospital
267 Grant Street
Bridgeport, CT 06610
(203) 384-3544

Relocate to sunny Southern California.

Christian Hospital Medical Center is an acute care facility located in one of the fastest growing areas with young families and industry.

Opportunities available for OB/GYN physicians in our new women's program from prenatal through postpartum starting December 1990. Be a part of our innovative professional team including complete medical and educational services. These positions boast a competitive benefits package and practice conditions.

The Christian Hospital Medical Center is situated in a growing area within easy reach of Riverside and San Diego, thus offering the best of small town hospitality and large city convenience. Loma Linda is with easy commuting distance for high risk clients.

Please feel free to send your confidential resume to:

Administrator

Equal Opportunity Employer

COPLEY HOSPITAL DELIVERS

If you do, too, perhaps you'd like to join us. You will be joining a medical staff of 38 primary care and specialty physicians at one of the finest small (53 bed) rural hospitals in the country.

Progressive, creative and award winning programs have made Copley an important name in rural health care. Near Stowe, Vermont, our special setting provides natural beauty and a variety of activities for an unusual population mix—both country and cosmopolitan.

Position available immediately for the right Board Certified or Board Eligible OB/GYN. If you think you're the physician we're looking for, send letter of application and curriculum vitae to Reginald Lavoie, Vice President of Planning & Clinical Services, Copley Hospital, RR #3, Box 760, Morrisville, Vermont 05661.

GROUP HEALTH PLAN

CHAIR, DEPARTMENT OF OBSTETRICS AND GYNECOLOGY

The Allentown Hospital–Lehigh Valley Hospital Center (TAH-LVHC), an 830-bed regional tertiary care teaching hospital is seeking an OB/GYN Chair. The hospital has 33 active OB/GYN staff physicians, including a gynecologic oncologist and reproductive endocrinologist. The current Chair, who will be leaving at the end of this year, is a perinatologist. The hospital is currently recruiting a maternal-fetal subspecialist. TAH-LVHC is a regional Level III Perinatal Center and a clinical campus of Hahnemann University in Philadelphia. Of over 3,300 births in 1989, 42% were in the high-risk category. The department is supported by a 20-bed Level III NICU and has an active OB/GYN clinic which experienced over 8,000 visits in 1989.

NEWLY-CREATED POSITION OF VICE CHAIR/DIRECTOR OF EDUCATION

In response to the continuing growth of the community and the expansion of the OB/GYN Department, TAH-LVHC is seeking its first full-time OB/GYN Vice Chair/Director of Education. The hospital has a fully-approved free-standing Residency Program with eight American-trained residents. A total of 70 residents and 400 medical students are trained at the hospital each year.

The hospital is located in Allentown, a cosmopolitan city one hour north of Philadelphia and one and one-half hours west of New York City. Interested board-certified candidates may send a curriculum vitae, in confidence, to **Headley S. White, Jr., M.D., Sr. V.P., Medical and Academic Affairs, c/o HealthSearch, 50 College Drive, Suite 323, Allentown, PA 18104. (215)778-7993.**

PERINATOLOGIST

Outstanding practice opportunity for a BC/BE perinatologist to join an established practice at Iowa's largest private teaching medical center. The hospital, a state designated Level III Perinatal Center, averages over 2,000 deliveries annually and has an active maternal and neonatal transport system. The medical center's Level III Neonatal Intensive Care Unit is staffed by four board certified neonatologists. Complete laboratory facilities are available including cytogenetic analysis of both amniotic fluid and trophoblastic tissue. The Antepartum Testing Unit is equipped with computer-based fetal monitors and a color flow Doppler ultrasound unit. Excellent financial and lifestyle opportunities are available to the qualified candidate. Please call 515/283-5911 or send CV to Mariann Clark, Medical Search Consultant, 1200 Pleasant Street, Des Moines, IA 50309.

MATERNAL-FETAL MEDICINE SPECIALIST

Join existing Maternal-Fetal Medicine Specialist and practice at Methodist Hospital of Indiana. Candidates must be fellowship trained in Maternal-Fetal Medicine or Perinatology.

Indianapolis hospital has over 1,100 beds, a Level III nursery, and a Pediatric ICU. This is an extremely busy, existing practice which also offers the opportunity for academics/research.

Compensation includes salary from Methodist Hospital plus private practice income. Total package of over $200,000 for the first year. Generous benefits package available. All interviewing and relocation expenses paid. Send CV or call:

MATERNAL-FETAL MEDICINE

The Allentown Hospital–Lehigh Valley Hospital Center, an 830-bed tertiary care center in eastern Pennsylvania, is seeking a physician to direct the maternal-fetal service (including Level II ultrasound and antenatal fetal diagnostic procedures) and provide leadership and medical education in maternal-fetal medicine. Applicants should be board-certified or active candidates for certification in maternal-fetal medicine.

TAH–LVHC sponsors a fully accredited OB/GYN Residency Program and is a clinical campus of Hahnemann University in Philadelphia, where the successful candidate will be eligible for faculty appointment. The hospital is a referral center for a population of close to one million people and is a Level III Perinatal Center; of over 3,300 deliveries performed last year, 42% were designated high-risk. The department is supported by a 20-bed Level III NICU and also provides a full range of services to women with subspecialists in both reproductive endocrinology and gynecologic oncology. (Our current maternal-fetal subspecialist, who is our department Chair, will be leaving at the end of the year.)

The hospital is located in Allentown, a prosperous and desirable area with excellent schools and diverse cultural and recreational opportunities, one hour north of Philadelphia and one and one-half hours west of New York City.

Please submit a curriculum vitae, in confidence, to: **Headley S. White, Jr., M.D., Sr. V.P. Medical and Academic Affairs, c/o HealthSearch, 50 College Drive, Suite 325, Allentown, PA 18104, (215) 778-7993.** Equal Opportunity Employer.

This is a two year accredited Fellowship program i which both clinical and research training are emphasized. Clinica material is drawn from the 3000 deliveries/year at St. John' Hospital Perinatal Center where fellows participate in a supervise in-depth experience in management and treatment of medical an obstetrical complications with emphasis on antenatal diagnosti procedures and ultrasound techniques. This flexible prograr incorporates a minimum six month period of full time research an accommodates various clinical/research objectives based on th fellow's individual goals. Fellows are encouraged to present paper and to represent the Maternal Fetal Medicine Division at nationa scientific meetings.

Application requests should be sent to:
Robert C. Kaufmann, M.D., Department of OB/GYN, Southern Illinoi University School of Medicine, P.O. Box 19230, Springfield, IL 62794. Phone: (217) 782-8240

DIRECTOR OF DEPARTMENT OF OBSTETRICS and GYNECOLOGY

St. Luke's/Roosevelt Hospital Center, a 1,315 bed teaching hospital on Manhattan's West Side, affiliated with the Columbia University College of Physicians and Surgeons, invites nominations and applications for a Director of the Department of Obstetrics and Gynecology. The Director is responsible for the clinical, academic and research programs at both the St. Luke's and Roosevelt sites which together serve a catchment populations of over 500,000 as well as a large referral base from well beyond this local community.

The successful candidate must qualify as a senior faculty member at Columbia University with demonstrated clinical and academic achievement. Administrative and leadership skills will also be required in order to maintain and foster the department's current accomplishments.

Curricula vitae will be considered in strictest confidence.

Sigurd Ackerman, M.D.
Chairman, Search Committee for a Director
of the Department of Obstetrics and Gynecology
ST. LUKE'S/ROOSEVELT HOSPITAL CENTER

Hospital Center

OB/GYN- SOUTHWESTERN MICHIGAN

OB/GYN to join another OB/GYN and a nurse-midwife in clinic practice. Average 600 deliveries per year. Opportunity has an excellent mix of GYN Pathology.

330-bed facility in a service area of 215,000 has 4 LDR's, 24-hour, in-house Anesthesia (Epidural Service), and a Level II nursery. Community is located on Lake Michigan and is 90 minutes from Chicago in Southwestern Michigan.

$150,000 base salary. Production bonus may increase income by another $50,000 to $100,000 the first year. Send CV or call:

JACKSON AND COKER

UNIVERSITY OF MIAMI
SCHOOL OF MEDICINE
DEPARTMENT OF OBSTETRICS & GYNECOLOGY

ASSISTANT/ASSOCIATE PROFESSOR OF CLINICAL OBSTETRICS & GYNECOLOGY

Opportunity available for M.D. who is board-certified or board-eligible in Maternal Fetal Medicine. Special interest in infectious disease is desirable but not required.

Applicant must be licensed to practice medicine in State of Florida, and have sufficient clinical experience to qualify for a full time faculty appointment.

Salary will be commensurate with training and experience. Compensation includes excellent fringe benefit and financial incentive plan.

Apply to:

Mary J. O'Sullivan, M.D.
Professor
Obstetrics & Gynecology, R-136
University of Miami
P.O. Box 016960
Miami, Florida 33101

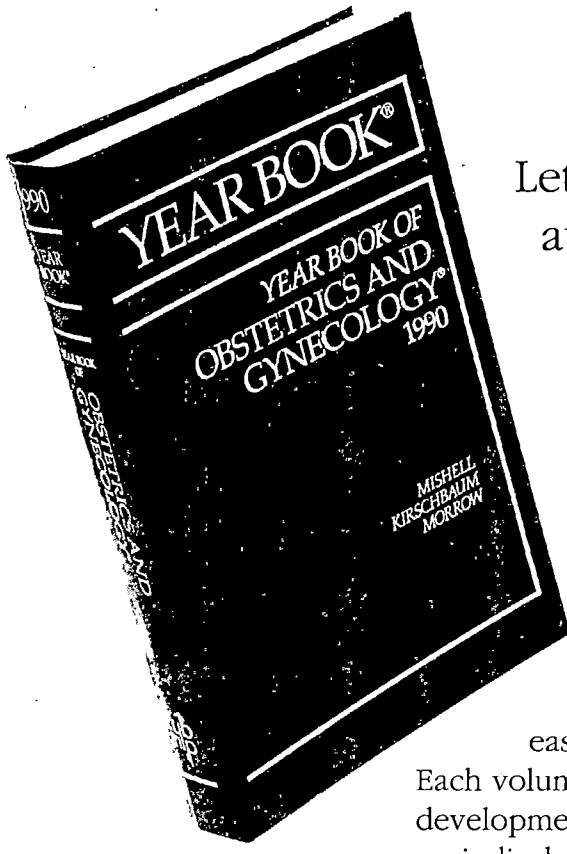
AN EQUAL OPPORTUNITY/AFFIRMATIVE ACTION EMPLOYER

LAS VEGAS—Seeking highly qualified board certified/eligible Ob/Gyn physicians to join our 60 physician multi-specialty group. Practice in America's Vacationland—mountain sports, water sports, world class entertainment. Enjoy affordable housing, no state income tax, excellent schools/colleges. High starting salaries, plus bonuses, no investment required. Benefits include malpractice insurance, paid vacation, relocation expenses, health and life insurance, retirement program, continuing medical education, dues, subscriptions, etc. Top tertiary hospitals.

If interested, call me at (702) 877-8638 or send your Curriculum Vitae to: Jerry Reeves, M.D., President, Southwest Medical Associates, P.O. Box 15645, Las Vegas, NV 89114.

FACULTY POSITION UNIVERSITY OF WASHINGTON

A University of Washington junior faculty position is available in the Gynecology Division in the Department of Obstetrics and Gynecology. Patient responsibility will involve both gynecologic outpatient and inpatient care. The individual will spend 60% time in clinical practice and the remaining time conducting medical student teaching, resident teaching and clinical research. Applicants must be board eligible or certified in obstetrics or gynecology. Fellowship or research experience is desirable. The position is immediately available.



Please send a curriculum vitae to:

David A. Eschenbach, M.D.
Department of Obstetrics and Gynecology, RH-20
University of Washington,
Seattle, WA 98195

An equal opportunity/affirmative action employer.

PERINATAL PATHOLOGIST AT NORTHWESTERN UNIVERSITY MEDICAL SCHOOL. The Department of Pathology of Northwestern University Medical School seeks applicants with subspecialty training and experience in perinatal pathology, for a full-time faculty position. The academic level of appointment and salary will be commensurate with prior experience and scholarly accomplishment. The Department is developing a perinatal program in conjunction with the Department of Obstetrics and Gynecology. The Prentice Women's Hospital of McGaw Medical Center currently has 5000 deliveries/year and has a high risk pregnancy program which serves greater metropolitan Chicago, the State of Illinois and adjacent States. Children's Memorial Hospital is also part of the Medical School and Department's teaching program. The Department of Pathology has active residency, fellowship, and graduate student training programs. The successful candidate will be skilled in relevant aspects of perinatal pathology, teaching, and conduct either clinical or basic research. Interested candidates should submit a curriculum vitae and 3 letters of reference by December 31, 1990 to: Dr. Larry Sherman, Department of Pathology, Northwestern Memorial Hospital, Superior Street and Fairbanks Court, Chicago, IL 60611.

Northwestern University is an Affirmative Action/Equal Opportunity Employer. Hiring is contingent upon eligibility to work in the United States.

Let our eminent medical authorities guide you through major new clinical advances

Introducing the

Year Book of Obstetrics & Gynecology®

This time-saving guide book makes it easy for you to keep current in your field. Each volume represents the year's most significant developments as reported in more than 800 journals and periodicals published worldwide. These selections are condensed to roughly a page in length, so you get all essential facts at a glance.

More importantly, the distinguished physician editors provide thoughtful, probing commentaries that explore the significance of each article while evaluating its practical implications for day-to-day practice.

Editors: Daniel R. Mishell, Jr., M.D.; Thomas H. Kirschbaum, M.D.; and C. Paul Morrow, M.D. **Contributing Editor**: William H. Hindle, M.D.

These books are published annually. For the convenience of its customers, Year Book enters each purchaser as a subscriber to future volumes and sends annual announcements of each volume approximately two months before publication. The new volume will be shipped upon publication unless you complete and return the cancellation notice attached to the announcement and it is received by Year Book within the time indicated (approximately 20 days after your receipt of the announcement). You may cancel your subscription at any time. The new volume may be examined on approval for 30 days and returned for full credit. Year Book will remove your name as a subscriber. Return postage is guaranteed by Year Book to the Postal Service.

Obstetrics and Gynecology Review Course

February 2-7, 1991 – Los Angeles
November 25-30, 1991 – Chicago

Now, your course with case-list reviews and mock oral exams

OBJECTIVES
- Increase basic knowledge and clinical skills in ob-gyn.
- Assist residents and fellows to organize study
- Prepare exam candidates to pass their tests.
- Provide practicing gynecologists with an update

METHODS
- HOME STUDY MATERIALS with questions and answers
- SEMINAR with projection slides and syllabus
- LABORATORY with microscopic slides
- PRACTICE EXAMS with oral and written parts

*"The faculty was outstanding. The most pleasant thing was learning a tremendous amount, not only from world-famous authorities but from people who are relatively unknown as well."**

TOPICS

Clinical Science
- Surgical Anatomy
- Embryology
- Radiology
- Genetics
- Teratology
- Anesthesiology
- Antibiotics

Pathology
- Vulva
- Vagina
- Cervix
- Endometrium
- Myometrium
- Ovary
- Placenta

Reproductive Endocrinology
- Contraception
- Infertility
- Amenorrhea
- Abnormal Bleeding
- Androgen
- Prolactin
- Menopause

Oncology
- Chemotherapy
- Vulva and Vagina
- Cervix
- Uterus
- Ovary
- Trophoblast
- Breast

Benign Gynecology
- Infectious Diseases
- Urinary Retention
- Urinary Incontinence
- Pediatric Gynecology
- Sexual Assault
- Ectopic Pregnancy
- Endometriosis

Maternal and Fetal Medicine
- Pharmacology
- Diabetes
- Hypertension
- Hematology
- Antepartum Testing
- Premature Labor
- Birth Trauma

*"Accommodations were comfortable...."**

GOALS AND LOCATION: This course for residents and practicing gynecologists is a comprehensive review and update offered in the winter, spring and fall. The fall course is more clinically oriented. Home study questions are sent upon registration. The course includes lectures with syllabus as well as an opportunity to purchase an unlimited number of optional extra one-on-one sessions with faculty to review your case lists or do mock oral exams. Past participants recommend repeating the course for half price immediately before exams. The course hotel is chosen in competetive bidding to achieve the best combination of bargain rates and excellent study environment.

*"...and those little extras...."**

LOWEST AIR FARES: Please call toll-free 1-800-548-8185 for group discounts.

*"...the most education for the money."**

FEES:
- Practicing Gynecologists: $720
- Residents and Fellows: $480
- Repeating course within 3 years: $360
- Case-list reviews and mock oral exams (half hour sessions): $ 70
- Private mock oral exams: $100
- Optional extra day Dec. 1 (more questions, answers and pathology lab): $15(
- **Add 10% for within 10 days of the course.**
- Attendees not in course hotel add $20/day
- A deposit of $50 will reserve your position

"...home study material was extremely helpful."

CANCELLATIONS: Refunds subject to $5 fee, will be made until the seminar begins

*"...remarkably complete and pleasant."**.

ORTHO-NOVUM® 777 Tablets

norethindrone/ethinyl estradiol

Smooth Sailing!

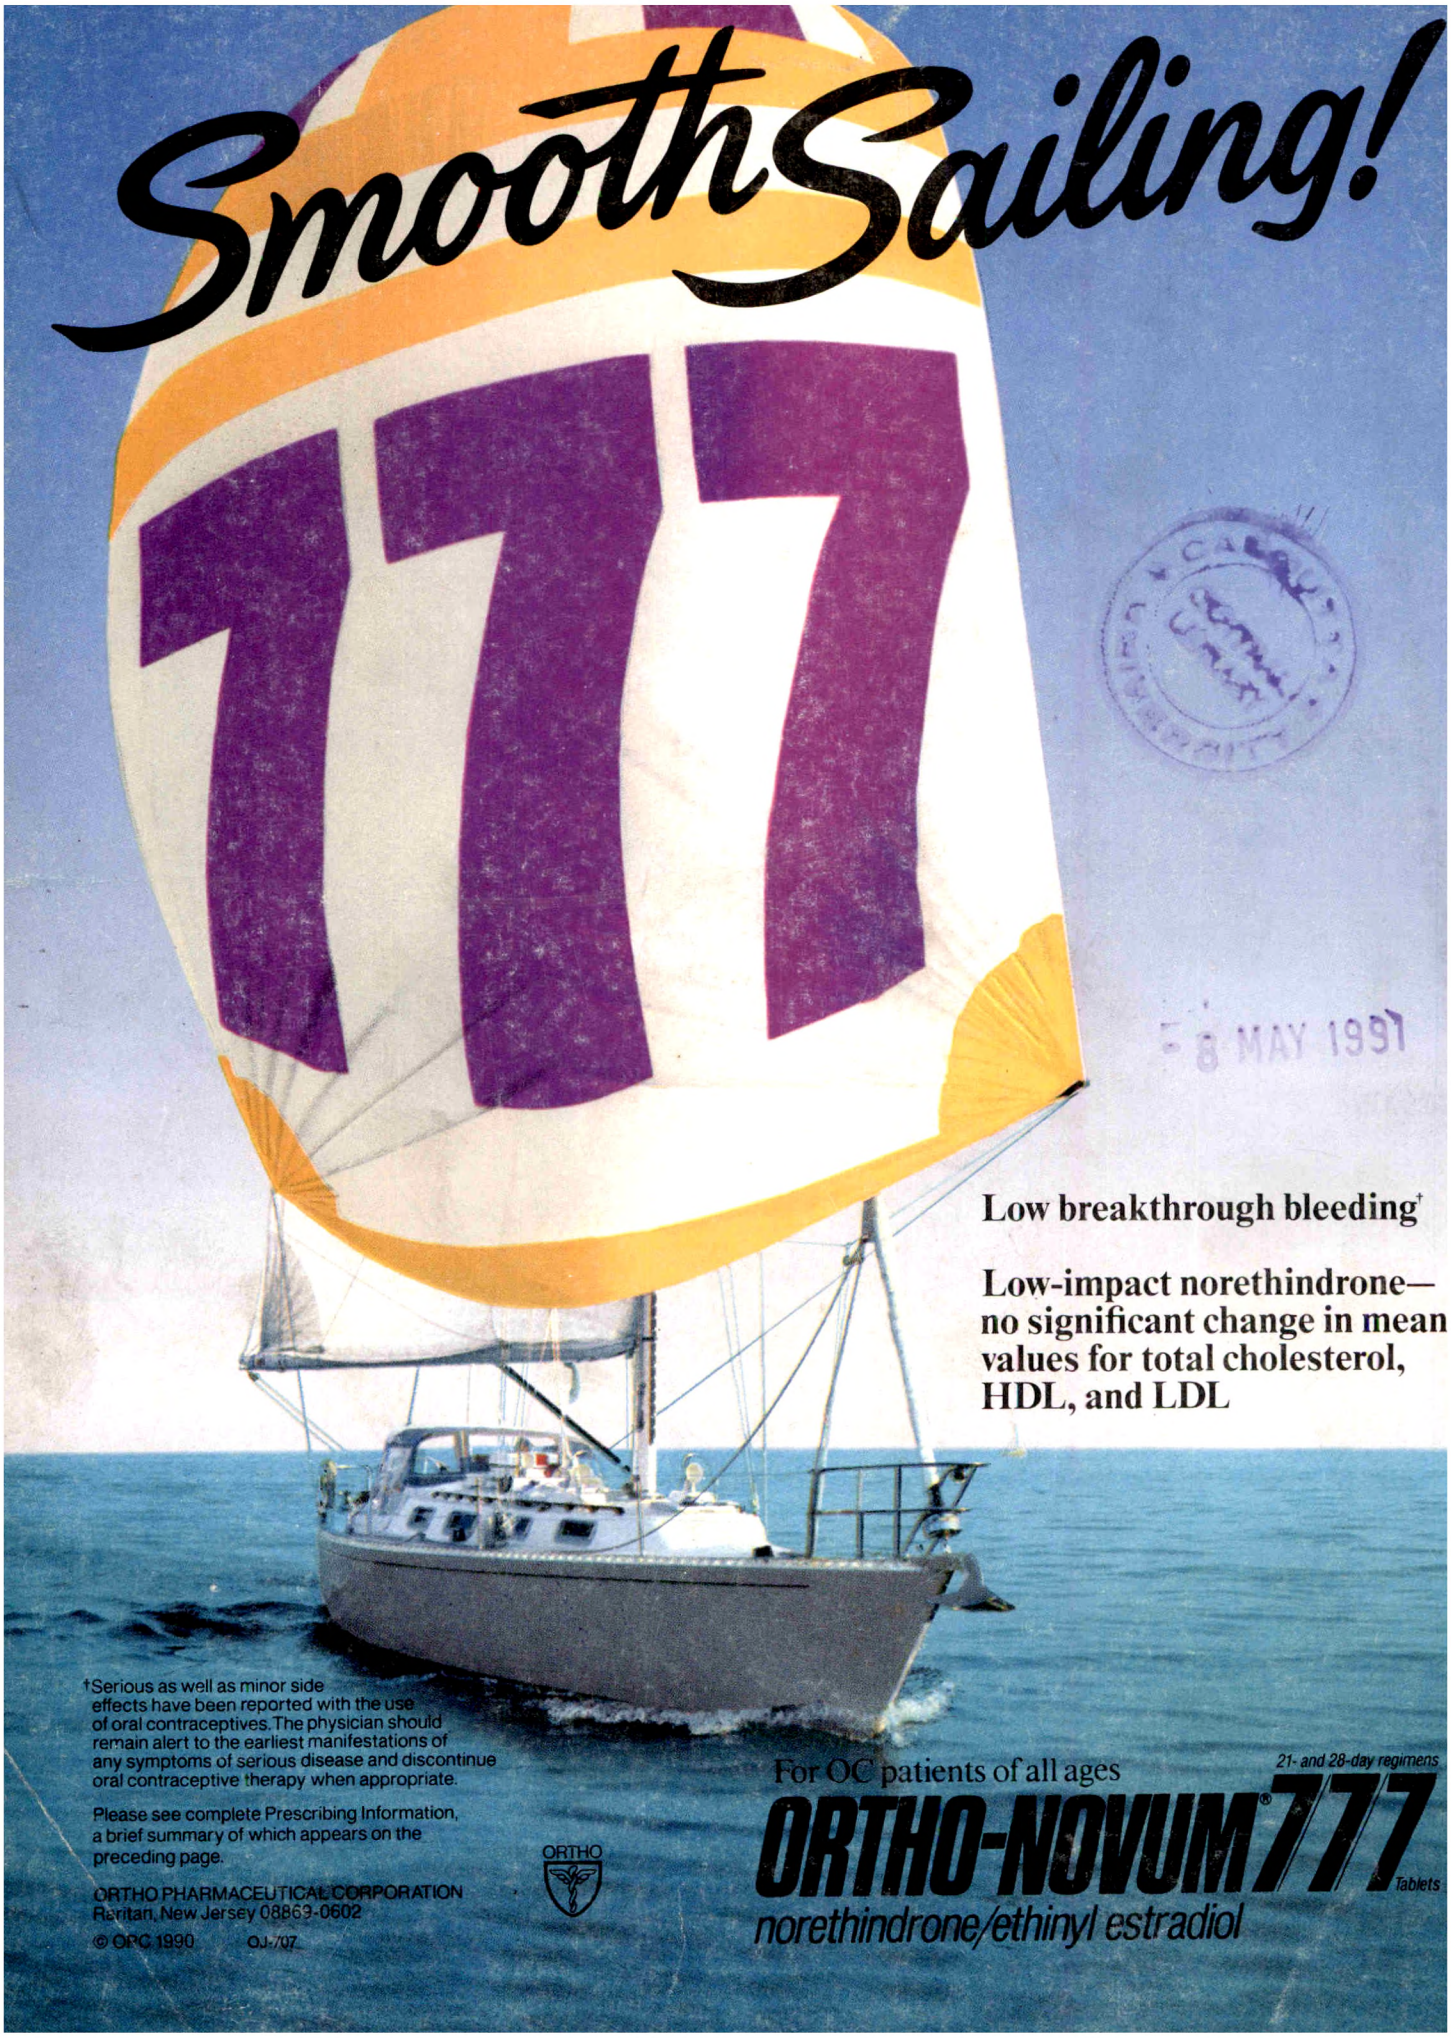
Each white tablet contains 0.5 mg norethindrone and 0.035 mg ethinyl estradiol. Each light peach tablet contains 0.75 mg norethindrone and 0.035 mg ethinyl estradiol. Each peach tablet contains 1 mg norethindrone and 0.035 mg ethinyl estradiol. Each green tablet in 28 day regimen contains inert ingredients.

IMPORTANT NOTE—This information is a BRIEF SUMMARY of the complete prescribing information provided with the product and therefore should not be used as the basis for prescribing the product. This summary was prepared by deleting from the complete prescribing information certain text, tables and references. The physician should be thoroughly familiar with the complete prescribing information before prescribing the product.

INDICATIONS AND USAGE: PREVENTION OF PREGNANCY.

CONTRAINDICATIONS: Oral contraceptives should not be used in women who currently have the following conditions: 1. Thrombophlebitis or thromboembolic disorders. 2. A past history of deep vein thrombophlebitis or thromboembolic disorders. 3. Cerebral vascular or coronary artery disease. 4. Known or suspected carcinoma of the breast. 5. Carcinoma of the endometrium or other known or suspected estrogen-dependent neoplasia. 6. Undiagnosed abnormal genital bleeding. 7. Cholestatic jaundice of pregnancy or jaundice with prior pill use. 8. Hepatic adenomas or carcinomas. 9. Known or suspected pregnancy.

WARNINGS



Cigarette smoking increases the risk of serious cardiovascular side effects from oral contraceptive use. This risk increases with age and with heavy smoking (15 or more cigarettes per day) and is quite marked in women over 35 years of age. Women who use oral contraceptives should be strongly advised not to smoke.

The use of oral contraceptives is associated with increased risks of several serious conditions including myocardial infarction, thromboembolism, stroke, hepatic neoplasia, and gallbladder disease, although the risk of serious morbidity or mortality is very small in healthy women without underlying risk factors. The risk of morbidity and mortality increases significantly in the presence of other underlying risk factors such as hypertension, hyperlipidemias, obesity and diabetes. Practitioners prescribing oral contraceptives should be familiar with the following information relating to these risks. The information contained in this brief summary is principally based on studies carried out in patients who used oral contraceptives with higher formulations of estrogens and progestogens than those in common use today. The effect of long term use of the oral contraceptives with lower formulations of both estrogens and progestogens remains to be determined. Throughout this brief summary epidemiological studies reported are of two types: retrospective or case control studies and prospective or cohort studies. Case control studies provide a measure of the relative risk of a disease, namely a *ratio* of the incidence of a disease among oral contraceptive users to that among nonusers. The relative risk does not provide information on the actual clinical occurrence of a disease. Cohort studies provide a measure of attributable risk, which is the *difference* in the incidence of disease between oral contraceptive users and nonusers. The attributable risk does provide information about the actual occurrence of a disease in the population. For further information, the reader is referred to a text on epidemiological methods. 1. THROMBOEMBOLIC DISORDERS AND OTHER VASCULAR PROBLEMS. a. Myocardial Infarction. An increased risk of myocardial infarction has been associated with oral contraceptive use. This risk is primarily in smokers or women with other underlying risk factors for coronary artery disease such as hypertension, hypercholesterolemia, morbid obesity, and diabetes. The relative risk of heart attack for current oral contraceptive users has been estimated to be two to six. The risk is very low under the age of 30. Smoking in combination with oral contraceptive use has been shown to contribute substantially to the incidence of myocardial infarctions in women in their mid-thirties or older with smoking accounting for the majority of excess cases. Mortality rates associated with circulatory disease have been shown to increase substantially in smokers, especially in those 35 years of age and older among women who use oral contraceptives. Oral contraceptives may compound the effects of well-known risk factors, such as hypertension, diabetes, hyperlipidemias, age and obesity. In particular, some progestogens are known to decrease HDL cholesterol and cause glucose intolerance, while estrogens may create a state of hyperinsulinism. Oral contraceptives have been shown to increase blood pressure among users (see section 9 in WARNINGS). Similar effects on risk factors have been associated with an increased risk of heart disease. Oral contraceptives must be used with caution in women with cardiovascular disease risk factors. b. Thromboembolism. An increased risk of thromboembolic and thrombotic disease associated with the use of oral contraceptives is well established. Case control studies have found the relative risk of users compared to non-users to be 3 for the first episode of superficial venous thrombosis, 4 to 11 for deep vein thrombosis or pulmonary embolism, and 1.5 to 6 for women with predisposing conditions for venous thromboembolic disease. Cohort studies have shown the relative risk to be somewhat lower, about 3 for new cases and about 4.5 for new cases requiring hospitalization. The risk of thromboembolic disease associated with oral contraceptives is not related to length of use and disappears after pill use is stopped. A two- to four-fold increase in relative risk of post-operative thromboembolic complications has been reported with the use of oral contraceptives. The relative risk of venous thrombosis in women who have predisposing conditions is twice that of women without such medical conditions. If feasible, oral contraceptives should be discontinued at least four weeks prior to and for two weeks after elective surgery of a type associated with an increase in risk of thromboembolism and during and following prolonged immobilization. Since the immediate postpartum period is also associated with an increased risk of thromboembolism, oral contraceptives should be started no earlier than four weeks after delivery in women who elect not to breast feed. c. Cerebrovascular diseases. Oral contraceptives have been shown to increase both the relative and attributable risks of cerebrovascular events (thrombotic and hemorrhagic strokes), although, in general, the risk is greatest among older (>35 years), hypertensive women who also smoke. Hypertension was found to be a risk factor for both users and non-users, for both types of strokes, and smoking interacted to increase the risk of stroke. In a large study, the relative risk of thrombotic strokes has been shown to range from 3 for normotensive users to 14 for users with severe hypertension. The relative risk of hemorrhagic stroke is reported to be 1.2 for nonsmokers who used oral contraceptives, 2.6 for smokers who did not use oral contraceptives, 7.6 for smokers who used oral contraceptives, 1.8 for normotensive users and 25.7 for users with severe hypertension. The attributable risk is also greater in older women. d. Dose-related risk of vascular disease from oral contraceptives. A positive association has been observed between the amount of estrogen and progestogen in oral contraceptives and the risk of vascular disease. A decline in serum high density lipoproteins (HDL) has been reported with many progestational agents. A decline in serum high density lipoproteins has been associated with an increased incidence of ischemic heart disease. Because estrogens increase HDL cholesterol, the net effect of an oral contraceptive depends on a balance achieved between doses of estrogen and progestogen and the activity of the progestogen used in the contraceptive. The activity and amount of both hormones should be considered in the choice of an oral contraceptive. Minimizing exposure to estrogen and progestogen is in keeping with good principles of therapeutics. For any particular estrogen/progestogen combination, the dosage regimen prescribed should be one which contains the least amount of estrogen and progestogen that is compatible with a low failure rate and the needs of the individual patient. New acceptors of oral contraceptive agents should be started on preparations containing 0.035 mg or less of estrogen. e. Persistence of risk of vascular disease. There are two studies which have shown persistence of risk of vascular disease for ever-users of oral contraceptives. In a study in the United States, the risk of developing myocardial infarction after discontinuing oral contraceptives persists for at least 9 years for women 40-49 years who had used oral contraceptives for five or more years, but this increased risk was not demonstrated in other age groups. In another study in Great Britain, the risk of developing cerebrovascular disease persisted for at least 6 years after discontinuation of oral contraceptives, although excess risk was very small. However, both studies were performed with oral contraceptive formulations containing 50 micrograms or higher of estrogens. 2. ESTIMATES OF MORTALITY FROM CONTRACEPTIVE USE. One study gathered data from a variety of sources which have estimated the mortality rate associated with different methods of contraception at different ages. These estimates include the combined risk of death associated with contraceptive methods plus the risk attributable to pregnancy in the event of method failure. Each method of contraception has its specific benefits and risks. The study concluded that with the exception of oral contraceptive users 35 and older who smoke and 40 and older who do not smoke, mortality associated with all methods of birth control is low and below that associated with childbirth. However, smokers 35 and older and non-smokers 40 and older who use oral contraceptives have a significant increase in mortality higher than those using other methods of birth control. These facts must be weighed in conjunction with failure rates for other methods and the risk associated with subsequent pregnancy. 3. CARCINOMA OF THE REPRODUCTIVE ORGANS. Numerous epidemiological studies have been performed on the incidence of breast, endometrial, ovarian and cervical cancer in women using oral contraceptives. While there are conflicting reports most studies suggest that use of oral contraceptives is not associated with an overall increase in the risk of developing breast cancer. Some studies have reported an increased relative risk of developing breast cancer, particularly at a younger age. This increased relative risk appears to be related to duration of use. Some studies suggest that oral contraceptive use has been associated with an increase in the risk of cervical intraepithelial neoplasia in some populations of women. However, there continues to be controversy about the extent to which such findings may be due to differences in sexual behavior and other factors. 4. HEPATIC NEOPLASIA. Benign hepatic adenomas are associated with oral contraceptive use, although the incidence of benign tumors is rare in the United States. Indirect calculations have estimated the attributable risk to be in the range of 3.3 cases/100,000 for users, a risk that increases after four or more years of use especially with oral contraceptives of higher dose. Rupture of benign, hepatic adenomas may cause death through intra-abdominal hemorrhage. Studies from Britain have shown an increased risk of developing hepatocellular carcinoma in long-term (>8 years) oral contraceptive users. However, these cancers are rare in the U.S. and the attributable risk (the excess incidence) of liver cancers in oral contraceptive users approaches less than one per million users. 5. OCULAR LESIONS. There have been clinical case reports of retinal thrombosis associated with the use of oral contraceptives. Oral contraceptives should be discontinued if there is unexplained partial or complete loss of vision; onset of proptosis or diplopia, papilledema, or retinal vascular lesions. Appropriate diagnostic and therapeutic measures should be undertaken immediately. 6. ORAL CONTRACEPTIVE USE BEFORE OR DURING EARLY PREGNANCY. Extensive epidemiological studies have revealed no increased risk of birth defects in women who have used oral contraceptives prior to pregnancy. The majority of recent studies also do not indicate a teratogenic effect, particularly in so far as cardiac anomalies and limb reduction defects are concerned, when taken inadvertently during early pregnancy. The administration of oral contraceptives to induce withdrawal bleeding should not be used as a test for pregnancy. Oral contraceptives should not be used during pregnancy to treat threatened or habitual abortion. It is recommended that for any patient who has missed two consecutive periods pregnancy should be ruled out before continuing oral contraceptive use. If the patient has not adhered to the prescribed schedule, the possibility of pregnancy should be considered at the time of the first missed period. Oral contraceptive use should be discontinued until pregnancy is ruled out. 7. GALLBLADDER DISEASE. Earlier studies have reported an increased lifetime relative risk of gallbladder surgery in users of oral contraceptives and estrogens. More recent studies, however, have shown that the relative risk of developing gallbladder disease among oral contraceptive users may be minimal. The recent findings of minimal risk may be related to the use of oral contraceptive formulations containing lower hormonal doses of estrogens and progestogens. 8. CARBOHYDRATE AND LIPID METABOLIC EFFECTS. Oral contraceptives have been shown to cause a decrease in glucose tolerance in a significant percentage of users. This effect has been shown to be directly related to estrogen dose. Progestogens increase insulin secretion and create insulin resistance, this effect varying with different progestational agents. However, in the non-diabetic woman, oral contraceptives appear to have no effect on fasting blood glucose. Because of these demonstrated effects prediabetic and diabetic women in particular should be carefully monitored while taking oral contraceptives. A small proportion of women will have persistent hypertriglyceridemia while on the pill. As discussed earlier (see WARNINGS 1a and 1d), changes in serum triglycerides and lipoprotein levels have been reported in oral contraceptive users. 9. ELEVATED BLOOD PRESSURE. An increase in blood pressure has been reported in women taking oral contraceptives, and this increase is more likely in older oral contraceptive users and with extended duration of use. Data from the Royal College of General Practitioners and subsequent randomized trials have shown that the incidence of hypertension increases with increasing progestational activity. Women with a history of hypertension or hypertension-related diseases, or renal disease, should be encouraged to use another method of contraception. If women elect to use oral contraceptives, they should be monitored closely and if significant elevation of blood pressure occurs, oral contraceptives should be discontinued. For most women, elevated blood pressure will return to normal after stopping oral contraceptives, and there is no difference in the occurrence of hypertension between former and never users. 10. HEADACHE. The onset or exacerbation of migraine or development of headache with a new pattern which is recurrent, persistent or severe requires discontinuation of oral contraceptives and evaluation of the cause. 11. BLEEDING IRREGULARITIES. Breakthrough bleeding and spotting are sometimes encountered in patients on oral contraceptives, especially during the first three months of use. Non-hormonal causes should be considered and adequate diagnostic measures taken to rule out malignancy or pregnancy in the event of breakthrough bleeding as in the case of any abnormal vaginal bleeding. If pathology has been excluded, time or a change to another formulation may solve the problem. In the event of amenorrhea, pregnancy should be ruled out. Some women may encounter post-pill amenorrhea or oligomenorrhea, especially when such a condition was preexistent. 12. ECTOPIC PREGNANCY. Ectopic as well as intrauterine pregnancy may occur in contraceptive failures. **PRECAUTIONS:** 1. PHYSICAL EXAMINATION AND FOLLOW UP. A complete medical history and physical examination should be taken prior to the initiation or reinstitution of oral contraceptives and at least annually during use of oral contraceptives. These physical examinations should include special reference to blood pressure, breasts, abdomen and pelvic organs, including cervical cytology, and relevant laboratory tests. In case of undiagnosed persistent or recurrent abnormal vaginal bleeding, appropriate diagnostic measures should be conducted to rule out malignancy. Women with a strong family history of breast cancer or who have breast nodules should be monitored with particular care. 2. LIPID DISORDERS. Women who are being treated for hyperlipidemias should be followed closely if they elect to use oral contraceptives. Some progestogens may elevate LDL levels and may render the control of hyperlipidemias more difficult. 3. LIVER FUNCTION. If jaundice develops in any woman receiving such drugs, the medication should be discontinued. Steroid hormones may be poorly metabolized in patients with impaired liver function. 4. FLUID RETENTION. Oral contraceptives may cause some degree of fluid retention. They should be prescribed with caution, and only with careful monitoring, in patients with conditions which might be aggravated by fluid retention. 5. EMOTIONAL DISORDERS. Women with a history of depression should be carefully observed and the drug discontinued if depression recurs to a serious degree. 6. CONTACT LENSES. Contact lens wearers who develop visual changes or changes in lens tolerance should be assessed by an ophthalmologist. 7. DRUG INTERACTIONS. Reduced efficacy and increased incidence of breakthrough bleeding and menstrual irregularities have been associated with concomitant use of rifampin. A similar association, though less marked, has been suggested with barbiturates, phenylbutazone, phenytoin sodium, and possibly with griseofulvin, ampicillin and tetracyclines. 8. INTERACTIONS WITH LABORATORY TESTS. Certain endocrine and liver function tests and blood components may be affected by oral contraceptives: a. Increased prothrombin and factors VII, VIII, IX, and X; decreased antithrombin 3, increased norepinephrine-induced platelet aggregability. b. Increased thyroid binding globulin (TBG) leading to increased circulating total thyroid hormone, as measured by protein-bound iodine (PBI), T4 by column or by radio-immunoassay. Free T3 resin uptake is decreased, reflecting the elevated TBG, free T4 concentration is unaltered. c. Other binding proteins may be elevated in serum. d. Sex-binding globulins are increased and result in elevated levels of total circulating sex steroids and corticoids; however, free or biologically active levels remain unchanged. e. Triglycerides may be increased. f. Glucose tolerance may be decreased. g. Serum folate levels may be depressed by oral contraceptive therapy. This may be of clinical significance if a woman becomes pregnant shortly after discontinuing oral contraceptives. 9. CARCINOGENESIS. See WARNINGS section. 10. PREGNANCY. Pregnancy Category X. See CONTRAINDICATIONS and WARNINGS sections. 11. NURSING MOTHERS. Small amounts of oral contraceptive steroids have been identified in the milk of nursing mothers and a few adverse effects on the child have been reported, including jaundice and breast enlargement. In addition, oral contraceptives given in the postpartum period may interfere with lactation by decreasing the quantity and quality of breast milk. If possible, the nursing mother should be advised not to use oral contraceptives but to use other forms of contraception until she has completely weaned her child. **INFORMATION FOR THE PATIENT: See Patient Package Insert. ADVERSE REACTIONS:** An increased risk of the following serious adverse reactions has been associated with the use of oral contraceptives (see WARNINGS section). Thrombophlebitis and venous thrombosis with or without embolism. Arterial thromboembolism. Pulmonary embolism. Myocardial infarction. Cerebral hemorrhage. Cerebral thrombosis. Hypertension. Gallbladder disease. Hepatic adenomas or benign liver tumors. The following adverse reactions have been reported in patients receiving oral contraceptives and are believed to be drug-related: Nausea. Vomiting. Gastrointestinal symptoms (such as abdominal cramps and bloating). Breakthrough bleeding. Spotting. Change in menstrual flow. Amenorrhea. Temporary infertility after discontinuation of treatment. Edema. Melasma which may persist. Breast changes: tenderness, enlargement, secretion. Change in weight (increase or decrease). Change in cervical erosion and secretion. Diminution in lactation when given immediately postpartum. Cholestatic jaundice. Migraine. Rash (allergic). Mental depression. Reduced tolerance to carbohydrates. Vaginal candidiasis. Change in corneal curvature (steepening). Intolerance to contact lenses. The following adverse reactions have been reported in users of oral contraceptives and the association has been neither confirmed nor refuted: Pre-menstrual syndrome. Cataracts. Changes in appetite. Cystitis-like syndrome. Headache. Nervousness. Dizziness. Hirsutism. Loss of scalp hair. Erythema multiforme. Erythema nodosum. Hemorrhagic eruption. Vaginitis. Porphyria. Impaired renal function. Hemolytic uremic syndrome. Acne. Changes in libido. Colitis. **OVERDOSAGE:** Serious ill effects have not been reported following acute ingestion of large doses of oral contraceptives by young children. Overdosage may cause nausea and withdrawal bleeding may occur in females.

SESSION III. HEPATIC METABOLISM OF ORAL CONTRACEPTIVE STEROIDS

Chairman: M. Orme

Interactions with oral contraceptives 2153
Kenneth Fotherby, PhD
London, England

The many factors that may affect the pharmacokinetics and pharmacodynamics of oral contraceptives and the interaction of the estrogen and gestagen components are considered.

Inhibition of oral contraceptive steroid–metabolizing enzymes by steroids and drugs 2159
F. Peter Guengerich, PhD
Nashville, Tennessee

The major oxidative pathway of 17α-ethinyl estradiol metabolism, 2-hydroxylation, is inhibited by several chemicals; gestodene is an inactivator in the human liver.

Formation, metabolism, and physiologic importance of catecholestrogens 2163
Peter Ball, Prof. Dr. med, and Rudolf Knuppen, Prof. Dr. Rer. Nat.
Lubeck, West Germany

Aromatic orthohydroxylation of primary estrogens, such as estradiol and ethinyl estradiol, is an important reaction in mammals.

SESSION IV. HORMONAL EFFECTIVENESS OF ORAL CONTRACEPTIVE STEROIDS

Chairman: M. Breckwoldt

Binding of oral contraceptive progestogens to serum proteins and cytoplasmic receptor 2171
Michael Juchem and Kunhard Pollow, MD, PhD
Mainz, West Germany

Progestogens that are used in oral contraceptives are characterized at the level of receptors as well as at the level of high-affinity steroid-binding serum proteins.

(Contents continued on page 6A)

Contents continued from page 5A

Pharmacokinetics and pharmacodynamics of oral contraceptive steroids: Factors influencing the steroid metabolism 2183
Claudia Jung-Hoffmann, MD, and Prof. Dr. Herbert Kuhl, PhD
Frankfurt am Main, Federal Republic of Germany

The pharmacokinetics of contraceptive steroids during treatment with low-dose oral contraceptives indicate that ethinyl estradiol and nortestosterone derivatives may inhibit steroid metabolism.

Prodrugs: Advantage or disadvantage? 2198
Jürgen Hammerstein, MD
Berlin, West Germany

The use of hormonal prodrugs instead of drugs results in minor pharmacokinetic, pharmacodynamic, and potency changes with limited clinical impact, if any.

SESSION V. CLINICAL IMPLICATIONS

Chairman: H. D. Taubert

Gastrointestinal disease and oral contraception 2204
Jürgen P. Hanker, MD
Münster, West Germany

Gastrointestinal disease may impair contraceptive protection by reducing the bioavailability of oral contraceptive steroids.

Influence of oral contraceptives on drug therapy 2208
Alexander T. Teichmann, Prof. Dr. med.
Göttingen, West Germany

Oral contraceptives can modify pharmacokinetics of various drugs mainly by inhibition of oxidative metabolism and stimulation of conjugation with acids and may also interfere with pharmacodynamics.

Oral contraception in disease states 2213
M. Breckwoldt, P. Wieacker, and F. Geisthövel
Freiburg im Breisgau, Germany

Absolute and relative contraindications to the use of oral contraceptives are presented and discussed, with special reference to long-term diseases.

Introduction

The purpose of an oral contraceptive is to inhibit ovulation reliably, to maintain good cycle control, and to cause minimal adverse effects. The response of individual women to a given formulation differs to a large degree. Although the pill producers and the medical boards and authorities are, in the first place, interested in average figures of efficacy, adverse effects, and mortality, women who take the pill and the practitioner who prescribes it, are faced with individual susceptibilities, responses, and side effects. For the past 30 years ago, choosing the most suitable formulation has remained for each woman a matter of experience. Undoubtedly all formulations, including low-dose preparations, are overdosed for most women, because they must suppress ovulation in all women.

The pill is a combination of two hormones that, as far as the dose is concerned, belong to the most potent drugs known. Although it has a large therapeutic margin and serious adverse effects are rare, liver damage, stroke, or thromboembolic disease during intake of an oral contraceptive is a vital question for the individual. Any attempt to individualize the prescription of oral contraceptives on a scientific basis is dependent on the pharmacokinetics of the estrogen and progestogen components, which show large variations from woman to woman and from day to day. Therefore one of the most important aims of research must be to investigate the factors that influence the pharmacokinetic properties of contraceptive steroids.

The history of the pill since the days of Pincus is characterized by not only empiricism but also by errors. The suspicion that the estrogen component is involved in the etiology of cardiovascular diseases has led to a continuous reduction in the dose, which was hampered from time to time by the assumption that there must be a threshold dose of ethinyl estradiol with respect to good cycle control (e.g., 50 μg 20 years ago or 30 μg today). In both cases reality proved it to be wrong, provided that the progestogen was chosen properly. We are still waiting for a new estrogen that has no toxic effects on the liver. The development of the progestogens was decisively influenced by the "beagle story," when derivatives of progesterone were unfoundedly suspected of causing breast cancer. Although the hepatic effects of this type of progestogen are admittedly much less than those of ethinylated nortestosterone derivatives, new courses were set for the development of the so-called "gonanes." By the same measure, as potency was increased, the dose was reduced, which was claimed to be progress because of a pretendedly less burden of hepatic metabolism. However, a comparison of the pharmacokinetics would easily demonstrate that this is very questionable. The gonanes are orally more potent because their elimination is slowed down, and the serum concentrations of new and very low-dose progestogens may reach very high values. There are some indications that the slow inactivation rate of nortestosterone derivatives is not primarily the result of a steric hindrance of enzymatic action by the ethinyl group, but rather of a direct inhibition of enzymes by the chemically activated ethinyl group.

Even though there is no doubt that contraceptive steroids in the blood are of much higher importance for the assessment of the effects and risks than the dose ingested, pharmacokinetics are of limited interest for most gynecologists and endocrinologists. One of the aims of the symposium on "Pharmacokinetics of Oral Contraceptive Steroids and Drug Interactions" was to focus attention on this topic. More than 10 years have passed since a similar workshop conference was held in Igls, Austria, in 1978, and among the 18 experts assembling in Salzburg on September 14 to 16, 1989, some participated in the meeting held 1 decade ago. Obviously, the questions and problems discussed in Salzburg in 1989 have not changed since 1978.

As with the workshop conference in Igls, Austria, in 1978, the symposium held in Salzburg in 1989 was sponsored by Organon, Munich. It was because of Mrs. Franz and Dr. Geissler (Organon GmbH, Munich) that the organizational setting and the preconditions for a successful meeting have been optimal. Moreover, the generous support from Organon GmbH (Munich) and Organon International bv (Oss, Netherlands) enabled the publication of all the papers presented at the symposium in this supplement to the AMERICAN JOURNAL OF OBSTETRICS AND GYNECOLOGY.

SESSION I. PHARMACOKINETICS OF ORAL CONTRACEPTIVE STEROIDS

Chairman: K. Fotherby

Pharmacokinetics of ethinyl estradiol and mestranol

Joseph W. Goldzieher, MD, and Steven A. Brody, MD
Houston, Texas

Pharmacokinetally, a 50 μg oral dose of mestranol (which itself is inactive) is bioequivalent to a 35 μg dose of ethinyl estradiol. Physiologically, mestranol ranges from 50% to 100% of the activity of ethinyl estradiol, depending on the endpoint chosen. Compounds such as these, which are metabolized with a first-pass effect and are enterohepatically recirculated, demonstrate large interindividual and intraindividual variability in their pharmacokinetics. Thus a given dose of ethinyl estradiol in one person may produce an effect equivalent to a substantially larger (or smaller) dose in another person. This wide variability confounds efforts to establish tight dose-response relationships, a point rarely considered in clinical or epidemiologic studies of these compounds. The circulating levels of ethinyl estradiol sulfates may be higher than those of free ethinyl estradiol itself. It has been thought that these sulfates represent a "reservoir" of ethinyl estradiol. Our studies show that this idea is untenable because the half-life of the sulfates is not long enough for such an effect. Differences in the pharmacokinetics of ethinyl estradiol and mestranol have been observed in studies of various populations. The reality of these group differences is affirmed by analyses of urinary metabolite patterns. (Am J Obstet Gynecol 1990;163:2114-9.)

Key words: Ethinyl estradiol, mestranol, pharmacokinetics

All oral contraceptives currently in use rely on ethinyl estrogens for their estrogenic component. The reason for this is the greatly increased pituitary-inhibiting activity relative to other estrogenic effects, that is imparted by the ethinyl group. In addition, studies have shown that the ethinyl estrogens act synergistically with the 19-nor progestins with respect to gonadotropin suppression. Whether a synergism of *non*-ethinyl estrogens with these progestins exists is uncertain. This amplification is the basis on which the contraceptive effectiveness of the very low–dose formulations rests, and the reason why the dosage in the original "sequential" regimens could not be lowered to currently desired levels.

Some of the adverse symptomatic effects of the estrogens are clearly dose related. Therefore it becomes important to have an in-depth understanding of their pharmacokinetics.

Mestranol

In vitro receptor studies[1] have demonstrated that mestranol is an inactive compound that becomes biologically active on conversion to ethinyl estradiol (EE). The degree of conversion varies with different species. Published human studies of the pharmacokinetics of EE derived from mestranol generally suffer from the small number of subjects used (usually <10) and from insufficient sampling frequency. Thus the general impression of a 50% conversion rate of mestranol to EE is based on rather uncertain grounds. In view of what is known today about the magnitude of interindividual and intraindividual variation with these compounds, a reinvestigation is clearly needed.

We[2] have recently examined the pharmacokinetic parameters derived from analysis of plasma EE levels after administration of a single dose of three bioequivalent norethindrone (1 mg)/EE (35 μg) formulations from different manufacturers, as well as three norethindrone (1 mg)/mestranol (50 μg) formulations from the same manufacturers. The protocol was designed as an open-label, three-way crossover study. Each subject received a two-tablet dose of a drug within the first 6 days of three consecutive menstrual cycles. This double dose was used to improve assay reliability. The drugs were assigned in a randomized sequence so that all three drugs were tested in each subject at a given estrogen dose. Twenty-four women took each of these EE-35 formulations; another 27 took the three mestranol-50 formulations. Some of the derived pharmacokinetic parameters are shown in Table I.

The data clearly show the delay in achieving maximum plasma EE levels derived from mestranol compared with EE as expected. Interestingly, the peak plasma concentration (C_{max}) values for EE derived from

	1/50ME	0.13 ± 0.10	0.18 ± 0.13	0.13 ± 0.10	0.15 ± 0.12
			$p = 0.04$		

Reproduced with permission from Brody JA, Turkes A, Goldzieher JW. Contraception 1989;40:269-84.

Values shown are mean ± SD for area under the plasma concentration/time curve ($AUC_{0\text{-}24}$) by the trapezoidal rule; peak plasma concentration (C_{max}); time to peak concentration (T_{max}); and the elimination rate constant (K_{el}).

*n = 24 × three trials.

†n = 27 × three trials.

Table II. Interindividual variability of EE plasma concentrations after administration of two 35 μg EE and two 50 μg mestranol pills

Parameter	*Mean ± SD*	*Range*	*CV (%)*
EE (35 μg EE pills)			
$AUC_{0/24}$ (pg-hr/ml)	1036 ± 483	284-2498	47
C_{max} (pg/ml)	174 ± 67	55-311	39
EE from mestranol (50 μg mestranol pills)			
$AUC_{0\text{-}24}$ (pg-hr/ml)	963 ± 544	215-2122	57
C_{max} (pg/ml)	175 ± 72	67-391	41

Data from Brody JA, Turkes A, Goldzieher JW. Contraception 1989;40:269-84.

CV, Coefficient variation.

Table III. Range of pharmacokinetic values for EE reported in the literature

$t_{1/2}$ (α)	0.5-2.4 hr
$t_{1/2}$ (β)	13.1-27.0 hr
$t_{1/2}$ (Ka)	0.2-0.4 hr
Bioavailability	0.38-0.48
K_{12}	0.182-0.249/hr
K_{21}	0.101-0.245/hr
K_{10}	0.193-0.309/hr
T_{max}	1-2 hr

Estimate of $t_{1/2}$ (α) has a wide range and needs further documentation.

Ranges of values indicated are derived from Newburger and Goldzieher.[6]

$t_{1/2}$ (α) is the half-life of drug disposition from the central to the peripheral compartment.

$t_{1/2}$ (β) is the elimination half-life.

$t_{1/2}$ (Ka) is the half-life of drug delivery to the central compartment, where Ka is the transfer rate constant in this direction.

K_{12} is the transfer rate constant from the central to the peripheral compartment; K_{21} is the transfer rate constant in the reverse direction.

K_{10} is the same as the elimination rate constant (K_{el}).

Bioavailability is calculated by dividing AUC after oral administration by AUC after intravenous administration with the same dose of drug.

T_{max} is the time of maximum plasma concentration of drug.

The theoretic model for these pharmacokinetic parameters is described in Goldzieher et al.[11]

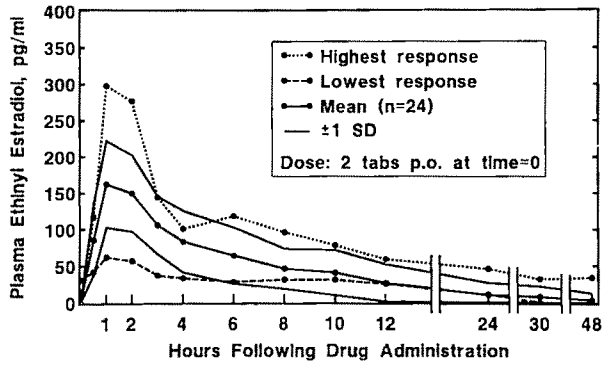

Fig. 1. Plasma EE contrations after administration of Norcept-E 1/35. A single dose of two tablets consisting of EE 35 μg/norethindrone 1 mg was given by mouth at time = 0. The mean ± SD is depicted along with highest and lowest individual responses. (Reproduced with permission from Brody SA, Turkes A, Goldzieher JW. Contraception 1989;40:269-84.)

50 μg of mestranol are identical with those derived from 35 μg of EE, both of which were given along with 1 mg of norethindrone. The mean area under the plasma concentration/time curve from 0 to 24 hours (AUC_{0-24}) values for EE derived from 50 μg of mestranol are clearly lower than those derived from 35 μg of EE as shown, but the very large intersubject variability keeps this difference from being statistically significant. From these data it may be concluded that EE from mestranol would yield about 70% of the C_{max} value of a similar dose of EE. Based on AUC_{0-24}, mestranol is somewhat less than 70% as bioavailable as EE. It appears that the usual estimate of 50% is probably low in terms of AUC.

The interindividual variation of plasma EE levels derived from EE or mestranol was similar: the coefficient of variation of AUC for EE was 47%; that for EE from mestranol was 57%. The coefficient of variation of C_{max} for EE was 39%; for EE derived from mestranol it was 41% (Table II).

These pharmacokinetic data are not necessarily concordant with pharmacodynamic observations. Studies of human endometrial response and measurements of hepatic synthesis of certain proteins suggest a potency of about 50% for mestranol compared with EE.[3-5] However, other studies of human endometrial response have found that the two compounds are bioequivalent over the range of 50 to 100 μg/day. Furthermore, studies of the effects on plasma gonadotropins, cortisol, testosterone, and androstenedione and their binding globulins and the effects on carbohydrate and lipid metabolism also found bioequivalence. These studies were conducted with estrogens alone rather than with commercial oral contraceptive formulations. It must be added, however, that these studies were not carried out on the numbers of patients we require in light of contemporary knowledge of interindividual variability.[6-10]

Table IV. Intraindividual variability of EE plasma concentration AUC_{0-24} after the administration of two 35 μg EE and 50 μg mestranol pills: three single-dose trials

	CV (%)	*Range**
EE (35 μg EE pills)	41	−66%-+71%
EE from mestranol (50 μg mestranol pills)	42	−70%-+92%

Data from Brody JA, Turkes A, Goldzieher JW. Contraception 1989;40:269-84.

CV, Coefficient of variation.

*The percent difference of high and low values from the mean of three trials per subject.

These findings are highly relevant to epidemiologic studies, which frequently analyze data sets in terms of the quantity of estrogen in contraceptive formulations without regard to the chemical nature of the estrogen. Thus some "high-dose" mestranol pills have a lower biologically active estrogen content than do some "low-dose" EE pills.[2]

EE

The literature on the pharmacokinetics of EE is substantial. There are large discrepancies in the values reported for the various parameters. These are probably because of limitations in sampling frequency, difficulties in measuring of plasma EE levels at clinically relevant dosages, and the effects of enterohepatic recirculation. The large interindividual variation seen with these drugs is a major confounding factor, accounting for the discrepant findings reported. Analysis of these difficulties has been presented elsewhere.[11] Our best estimate of the relevant pharmacokinetic parameters is shown in Table III. As Table III indicates, the half-lives for EE ($t_{1/2}\alpha$ and $t_{1/2}\beta$) have a very wide range. Oral bioavailability is relatively low, in the range of 38% to 48%. The transfer constants (K_{12}, K_{21}, and K_{10}) and the time to peak concentration are also quite variable. Our estimates of AUC_{0-24}, C_{max}, T_{max}, and K_{el} for a 50 μg dose from a large pharmacokinetic study are shown in Table II.

Large interindividual variation in the pharmacokinetics of EE is well recognized,[12] but has not been documented in studies with adequate sample size. The very large coefficients of variation of two parameters are presented in Table II. Fig. 1 illustrates the plasma levels for the mean, highest, and lowest responders in a group of 24 subjects given a 70 μg dose of EE. An analysis of time-integrated drug levels confirmed that the three commercial formulations tested were bioequivalent. Therefore the study design permitted an examination of intraindividual variation for single doses, an issue that has not been previously addressed (Table IV). For

both the 35 μg EE and the 50 μg mestranol preparations, there was a large intraindividual coefficient of variation: 41% to 42%. Within individual subjects the range of AUC varied enormously, from −70% to +92% of the mean of the three trials. Typical examples of this variability are shown in Table V. The unexpectedly large intraindividual variance, which showed no product-specific tendency, is apparent from the table. Moreover, the rank order of values for AUC_{EE} in the three trials per individual does not correlate with the rank order of the three results for AUC_{NET} (norethindrone), a point that has already been made by Fotherby.[13]

A prevailing opinion has been that the conjugates of

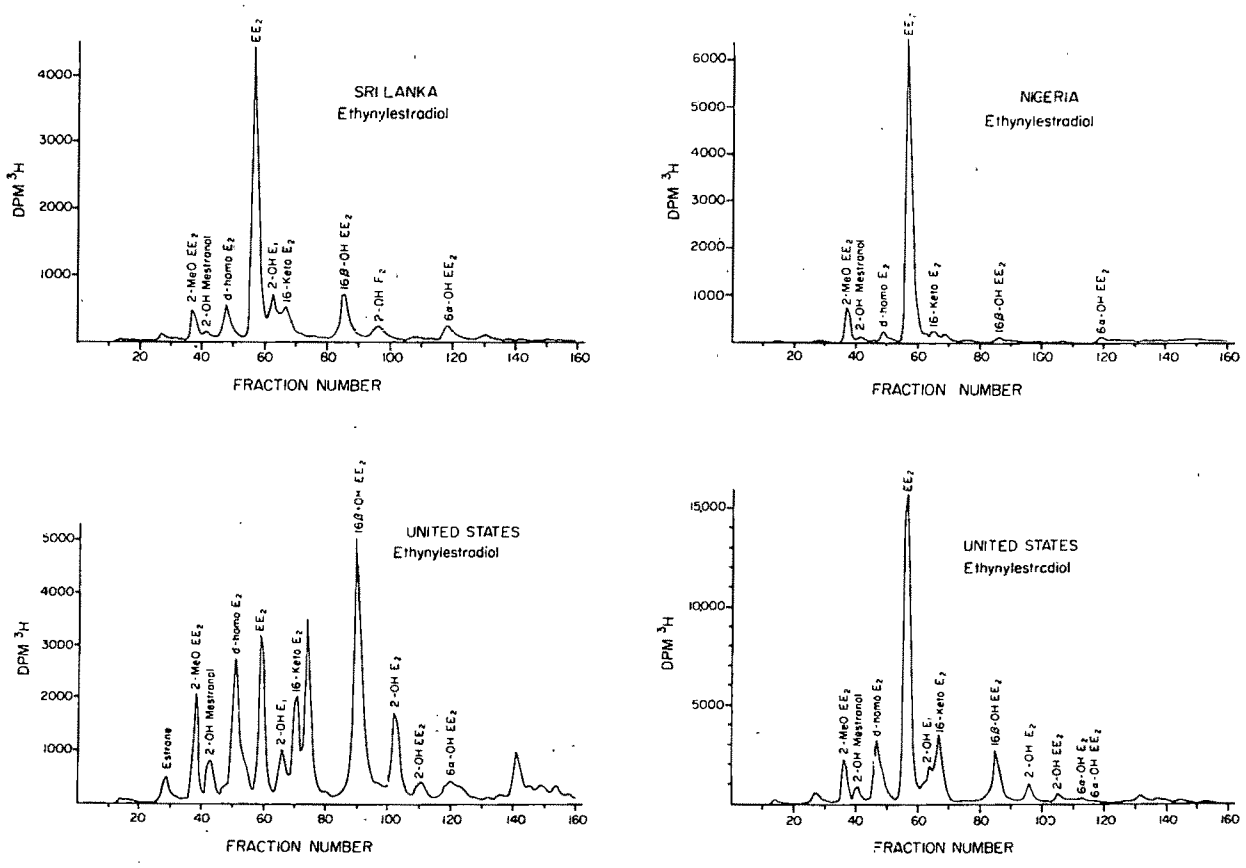

Fig. 3. Representative patterns of urinary mestranol and EE metabolites in women from Sri Lanka, Nigeria and the United States. High-performance liquid chromatography Chromegaprep Diol column, 9.6 mm by 50 cm; 10 μ; flow-7.5 ml/min; pressure, 1000 psi; linear gradient, 2.25% to 15% isopropanol in heptane in 158 minutes, scintillation counting of 1-minute fractions. Results from the two U.S. women illustrate the wide range of oxidative metabolism seen in this population. (Reproduced with permission from Butterworth-Heinemann. Williams MC, Goldzieher JW. Steroids 1980;36:255-82.)

EE, specifically the 3-sulfates, have relatively long half-lives and through enterohepatic recirculation might be deconjugated to provide a slow-release reservoir of EE. We have synthesized the various sulfates and have carried out clinical trials with these substances. A detailed analysis of the pharmacokinetic parameters has been published.[14] In summary, only 3.4% of intravenously administered and 11.4% of orally administered 17-sulfate appeared in the blood as free EE; with the 3-sulfate the conversion rates were 13.7% and 20.7%, respectively, which suggests that the sulfates are not important reservoirs. Moreover, the half-lives of free and sulfoconjugated EE are similar, ranging from 8.8 to 11.2 hours. Finally, the $t_{1/2}$ of the 17-sulfates after intravenous administration was similar to that of free EE. As expected, much more individual variation was encountered with oral administration than with the intravenous route. This phenomenon was apparent for both the 3- and 17-sulfates, as reflected in measurement of the total circulating EE sulfates.

Ethnic differences

Several investigators[15-17] have studied the pharmacokinetics of contraceptive steroids in various populations. Substantial differences in bioavailability have been noted. In comtemporary perspectives, the sample sizes studies and the blood sampling schedules used raise questions about the impact of interindividual variability as a possible confounding factor in the interpretation of these data. Although evidence of quantitative differences between populations is perhaps now less certain than was formerly thought, qualitative studies unequivocally support the conclusion that these population differences are real. In published studies[18] we have analyzed the pattern of urinary conjugates (glucuronides and sulfates) of EE after oral administration of radioactively labeled material to women in the United States, Sri Lanka, and Nigeria. In the three populations studied, the proportions of glucuronides and sulfoconjugates were similar: about 70% and 18%, respectively. However, the patterns of glucuronide con-

jugates seemed to differ. Further evidence of metabolic differences between populations can be demonstrated by examination of the oxidative metabolites of EE itself.

High-performance liquid chromatography profiling permits high-resolution identification of the various metabolites of EE (Fig. 2). There was a consistent difference, with Nigerian women (n = 10) displaying the least, Sri Lanka women (n = 10) intermediate, and American women (n = 6) the highest degree of oxidative metabolism, as evidenced by multiple chromatographic peaks identifying distinct metabolic products (Fig. 3). Such findings rule out the possibility that the observed pharmacokinetic differences between ethnic groups were from the confounding effects of interindividual variation. More important, they raise interesting questions regarding ethnic differences in the enterohepatic metabolism of EE. Further studies will be needed to address the role of nutritional factors, intestinal bacterial flora, genetic steroid-metabolic differences, and other as yet undiscovered influences on the metabolism of these compounds.

Pharmacokinetics of the contraceptive steroids levonorgestrel and gestodene after single and multiple oral administration to women

Wilhelm Kuhnz, PhD
Berlin, West Germany

Little is known about the pharmacokinetics of the two progestins levonorgestrel and gestodene during long-term administration compared with single-dose pharmacokinetics. The predictive value of single-dose administration for the pharmacokinetic behavior of a progestin during long-term treatment was investigated for two triphasic oral contraceptives. One contained levonorgestrel and the other gestodene, each in combination with ethinyl estradiol. In eight Japanese women who received the levonorgestrel-containing formulation over a treatment cycle, steady-state trough levels of levonorgestrel were higher than those obtained by computer simulation based on single-dose administration. An analogous observation was made in a group of 10 white women who received the gestodene-containing formulation. A close correlation between gestodene and sex hormone–binding globulin concentrations was demonstrated for eight subjects; the other two patients already had initially high sex hormone–binding globulin levels. Ethinyl estradiol–induced production of sex hormone–binding globulin seems to be a major factor that contributes to the accumulation of the two progestins in the plasma. Computer simulation, based on single-dose pharmacokinetics, allows an estimation of this contribution. (AM J OBSTET GYNECOL 1990;163:2120-7.)

Key words: Pharmacokinetics, synthetic progestins, long-term administration, steady-state concentrations, sex hormone–binding globulin

Levonorgestrel (LNG) and gestodene (GEST) are two synthetic progestins that are used in combination with ethinyl estradiol (EE_2) as oral contraceptives. Whereas LNG has been used for many years, GEST was introduced only a few years ago, and accordingly, a fairly large number of clinical pharmacokinetic studies have been performed with LNG-containing oral contraceptives, whereas a comparatively smaller number of analogous studies have been reported for GEST. Consequently, the pharmacokinetic characteristics of LNG after single-dose administration (intravenous and oral) are well known,[1] whereas analogous information on the pharmacokinetics of GEST has become available more recently.[2, 3] Compared with single-dose pharmacokinetics, much less published data are available on the administration of both progestins throughout a whole treatment cycle in healthy women.[3, 4, 9]

Because single-dose pharmacokinetics of a particular progestin hardly reflects the real situation of women taking an oral contraceptive for long durations, usually for many years, at least one important question must be addressed: Is the pharmacokinetic profile of a particular progestin the same after single- and multiple-dose administration or, in others words, is it possible to simply predict the pharmacokinetic behavior of a progestin during long-term treatment from the characteristics obtained after the administration of a single dose?

In this article this issue will be discussed for two triphasic oral contraceptives, one containing LNG and the other GEST, in combination with EE_2 as the estrogenic component.

Material and methods

Study design: Study I. This study was made up of two parts. The first included a group of seven healthy Japanese women between 22 and 34 years old, who received a single-coated tablet of each of the three dosage forms of the triphasic formulation (Triquilar) at the adequate time of the cycle (days 1, 7, and 13).

Blood samples were taken at the following times: before administration and 0.5, 1, 2, 3, 4, 8, and 24 hours after drug intake.

The second part of the study included eight healthy Japanese women between 21 and 35 years, who received the triphasic formulation during a whole cycle according to the following schedule: days 1 through 6: 0.05 mg LNG + 0.03 mg EE_2; days 7 through 11: 0.075 mg LNG + 0.04 mg EE_2; and days 12 through 21: 0.125 mg LNG − 0.03 mg EE_2.

Blood samples were taken during this period at the

Table I. Pharmacokinetic parameters (mean values) of LNG obtained from seven Japanese women who received three single-coated tablets of the triphasic oral contraceptive at adequate times during one cycle; parameters were calculated on the basis of an open two-compartment model; concentration values of LNG obtained after single administration of 0.05 mg LNG + 0.03 mg EE_2 were not suitable for model-fitting and therefore were not included

Parameter	*Dose of LNG (mg)*	
	0.075	*0.125*
C_{max} (ng/ml)	1.6	2.6
t_{max} (hr)	1.0	1.2
AUC (0-24 hr) (ng · ml^{-1} · hr)	8.5	17.1
AUC (ng · ml^{-1} · hr)	11.2	20.0
$t^{*}_{1/2}$ (hr)	13.1	13.1
V_{SS} (l)	90.6	85.0
Cl (ml · min^{-1} · kg^{-1})	2.0	1.9

V_{SS}, Apparent volume of distribution at steady state; *Cl*, clearance.

*Terminal half-life calculation was based on two concentration values only.

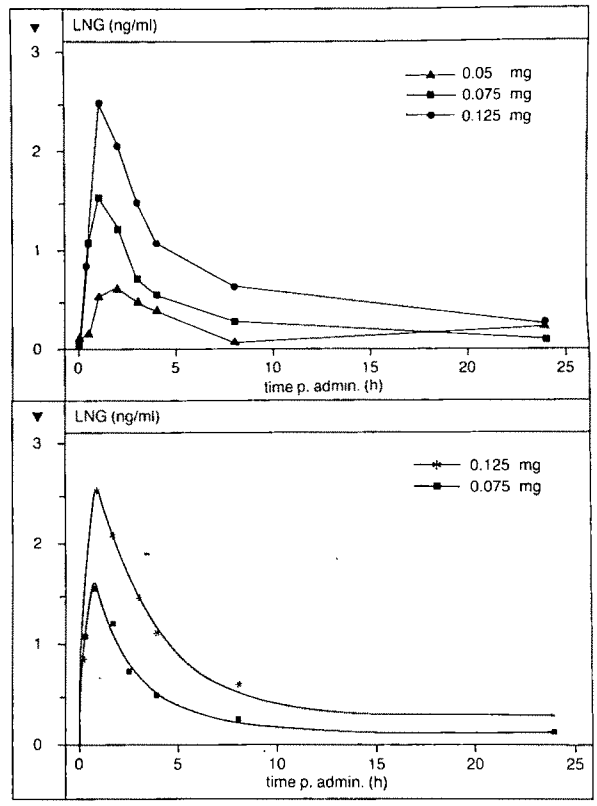

Fig. 1. Mean concentrations of LNG in plasma of seven Japanese women who received single doses of 0.05, 0.075, and 0.125 mg of LNG as coated tablets of a triphasic oral contraceptive at adequate times (days 1, 7, and 13) of the cycle. Directly obtained LNG concentration/time curves *(top)* are presented along with curves fitted on the basis of an open two-compartment model *(bottom)*.

following times: days 2, 4, 6, 8, 10, 12, 16, 18, and 20 before drug administration, and day 21 before drug administration and 0.5, 1, 2, 4, 8, 24, and 48 hours after drug intake.

All blood samples were collected in heparinized tubes and centrifuged, and plasma samples were frozen at −20° C until analysis.

Study design: Study II. This study was designed as an open investigation with 10 healthy white women between 23 and 39 years, who received a single-coated tablet of the triphasic preparation (Milvane) that contained 0.1 mg of GEST together with 0.03 mg of EE_2 on day 21 of a pretreatment cycle.

Blood samples were taken at the following times: before administration and 0.5, 1, 1.5, 2, 4, 6, 8, 10, 12, 24, 48, and 72 hours after drug intake.

After a wash-out phase of 7 days, the same women received, in the second part of the study, the triphasic formulation during a whole cycle: days 1 through 6: 0.05 mg GEST + 0.03 mg EE_2; days 7 through 11: 0.07 mg GEST + 0.04 mg EE_2; and days 12 through 21: 0.1 mg GEST + 0.03 mg EE_2.

Blood samples were taken at the following times: days 2 and 7: before and 0.5, 1, 1.5, 2, 4, 6, 8, and 12 hours after drug administration, and day 21: before and 0.5, 1, 1.5, 2, 4, 6, 8, 12, 24, 48, 72, and 96 hours after drug intake.

Additional blood samples were obtained on days 3, 5, 8, 10, 12, 14, 16, 18, and 20 before drug administration. All blood samples were kept at 4° C until coagulation; the serum was separated and stored at −20° C until analysis.

Analytic determinations. LNG was determined in all plasma samples of study I by a specific radioimmunoassay.[5] The serum samples of study II were analyzed for total concentration of GEST by a specific radioimmunoassay.[6] The free fraction of GEST, as well as the distribution of GEST over the serum-binding proteins albumin and sex hormone–binding globulin (SHBG), was determined by ultrafiltration[7] with and without heat treatment of the serum samples.[8]

In study II SHBG and cortisol-binding globulin (CBG) concentrations were measured by radioimmunologic means with two commercially available assay kits (SHBG: Diagnostic Products Corp., Los Angeles, Calif.; CBG: IRE Medgenix, Fleurus, Belgium).

Pharmacokinetic evaluation. Plasma concentrations of LNG, which were obtained during study I, were used for the model-free evaluation of maximum drug-concentration (c_{max}), time of maximum concentration (t_{max}), and area under the curve (AUC). In addition, the LNG

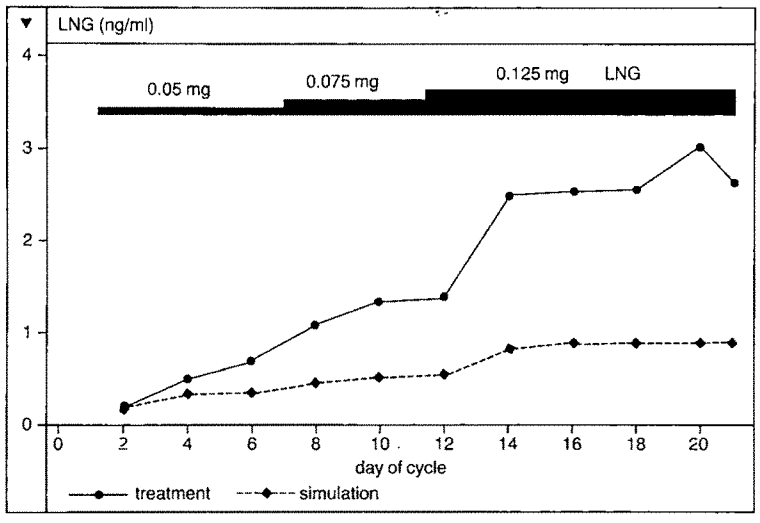

Fig. 2. Mean trough concentrations of LNG in plasma of eight Japanese women who received the triphasic oral contraceptive during one cycle. Experimentally measured and computer-simulated values are presented.

concentrations in plasma obtained after single-dose administration were evaluated by model-fitting (TOPFIT, Thomae GmbH, Biberach, West Germany) on the basis of an open two-compartment model. The serum concentrations of GEST obtained in study II were evaluated by model-fitting only. Apparent oral clearances and volumes of distribution were calculated for both progestins assuming 100% bioavailability.[2, 5, 10] The data obtained by model-fitting were used for the simulation of progestin concentrations in plasma (serum) during treatment with the respective triphasic formulations over a whole treatment cycle.

Accumulation factors were calculated as follows:

$$R = \frac{1}{1 - e^{\left(-\frac{\ln 2}{t_{1/2}} \cdot \tau\right)}}$$

$$R^* = \frac{C_{ss}^{min}\ (TC)}{C_{ss}^{min}\ (SC)}$$

where $t_{1/2}$ = terminal half-life; τ = dosing interval; C_{ss}^{min} = minimum concentration at steady state; TC = treatment cycle; and SC = simulated treatment cycle.

$$R^{**} = \frac{AUC\ (0\text{-}24\ hr)\ TC}{AUC_{SD}}$$

where SD = single dose.

Results

Study I: Pharmacokinetics of LNG after single-dose administration to Japanese women. The maximum concentration values of LNG, which were observed in the plasma of the seven women after single oral administration of the three different dosages (0.05, 0.075, and 0.125 mg of LNG), were 0.72 ± 0.34 ng/ml, 1.83 ± 0.61 ng/ml, and 2.74 ± 0.96 ng/ml, respectively. The corresponding t_{max} values were 2 ± 1 hour, 1.1 ± 0.7 hour, and 1.1 ± 0.6 hour, respectively. The observed AUC (0 to 24 hours) − values were 5.0 ± 4.1 ng * ml^{-1} * hr, 8.8 ± 5.3 ng * ml^{-1} * hr, and 17.1 ± 6.4 ng * ml^{-1} * hr, respectively. The time course of LNG levels in the plasma is shown in Fig. 1.

The mean LNG concentration values in plasma obtained after the administration of a single dose of 0.075 and 0.125 mg of LNG, respectively, were fitted on the basis of an open two-compartment model (Fig. 1). The derived pharmacokinetic parameters were identical to those determined without model-fitting (Table I).

A computer simulation of LNG trough levels in plasma during a 21-day treatment period was performed on the basis of those pharmacokinetic parameters that were obtained with high-dose LNG (0.125 mg) except that the terminal half-life was set to a value of 22 hours, which represented the experimentally observed value at the end of one treatment cycle in the second part of study I.

The result of this simulation is presented in Fig. 2, along with the experimentally obtained concentration values. The comparison of both curves demonstrated the following: (1) that simulated trough levels of LNG increased during treatment, reaching steady state on day 16 of treatment, and (2) that experimentally measured LNG trough levels closely followed simulated ones; however, they increased more markedly and reached a considerably higher plateau during the last week of treatment. Both curves demonstrate an increase in LNG plasma levels during 1 month of treatment.

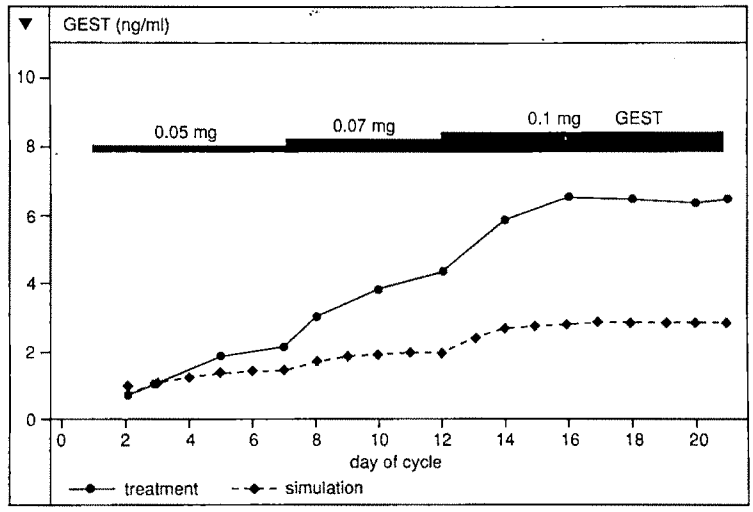

Fig. 3. Mean trough concentrations of GEST in the serum of 10 white women who received a GEST-containing triphasic oral contraceptive during one cycle. Experimentally measured and computer-simulated values are presented.

Table II. Pharmacokinetic parameters of LNG (mean ± SD) of eight Japanese women who received the triphasic formulation during one treatment cycle; data were calculated without model-fitting

Parameter	*Day 21 of treatment*
C_{max} (ng/ml)	6.2 ± 2.1
t_{max} (hr)	1.3 ± 0.5
AUC (0-24 hr) (ng · ml^{-1} · hr)	80.7 ± 34.8
AUC (ng · ml^{-1} · hr)	154.2 ± 69.7
$t_{1/2}$ (hr)	22.1 ± 5.7

Table III. Pharmacokinetic parameters of GEST (mean ± SD) obtained by model-fitting based on total and free concentrations in serum after single oral administration of a coated tablet containing 0.1 mg of GEST together with 0.03 mg of EE_2 on day 21 of a pretreatment cycle to 10 women

Parameter	*Total GEST*	*Free GEST*
C_{max} (ng/ml)	7.2 ± 3.2	0.09 ± 0.04
t_{max} (hr)	1.3 ± 1.1	1.3 ± 1.1
AUC (0-24 hr) (ng · ml^{-1} · hr)	50.6 ± 22.9	0.65 ± 0.25
AUC (ng · ml^{-1} · hr)	74.3 ± 37.5	0.97 ± 0.46
$t_{1/2}$ (hr)	15.8 ± 4.9	15.9 ± 5.4
V_{ss} (l)	32.2 ± 19.4	2242 ± 974
Cl (ml · min^{-1} · kg^{-1})	0.48 ± 0.25	34.7 ± 15.8

V_{ss}, Apparent volume of distribution at steady state; *Cl*, clearance.

An accumulation factor (R) of 1.9 can be calculated for LNG from a terminal half-life of 22 hours and a dosing interval of 24 hours. However, this only applies if accumulation is determined only by the terminal half-life of the drug and the dose interval chosen. If this was the case, the ratio (R*) of experimentally determined and simulated steady-state trough levels should be unity. Likewise, the ratio (R**) of AUC obtained on day 21 of the pretreatment cycle and AUC (0 to 24 hours) obtained on day 21 of the treatment cycle should also be unity. However, a value of 2.9 was calculated for the former and a value of 4.0 for the latter ratio.

Study I: Pharmacokinetics of LNG after multiple dose administration to Japanese women. Mean trough concentrations of LNG, which were measured during the treatment cycle, reached a steady state on about day 16 (Fig. 2).

On the last day of treatment (day 21), maximum concentrations of LNG in the plasma were observed 1.3 ± 0.5 hour after administration and amounted to 6.2 ± 2.1 ng/ml.

Postmaximum drug concentrations in plasma declined, with a mean half-life of disposition of 22.1 ± 5.7 hours. The AUC (0 to 24 hours) was 80.7 ± 34.8 ng * ml^{-1} * hr (Table II).

Study II: Pharmacokinetics of GEST after single-dose administration to white women. The maximum concentration values of GEST, which were observed in the serum of the 10 women after a single oral administration of 0.1 mg of GEST together with 0.03 mg of EE_2, were observed after 1.3 ± 1.1 hour and amounted to 7.2 ± 3.2 ng/ml. The terminal half-life of disposition was 15.8 ± 4.9 hours. The AUC was 74.3 ± 37.5 ng * hr * ml^{-1}. Total serum clearance was calculated to 0.48 ± 0.25 ml * min^{-1} * kg^{-1} (Table III). Protein binding of GEST and drug distribution over the binding proteins were determined before drug administration and 1 and 10 hours after drug intake, and they were identical in all cases. The free fraction of GEST

Table IV. Protein binding of GEST and concentration of SHBG and CBG (mean ± SD) in the serum of 10 women on day 21 of a pretreatment cycle and on day 21 of treatment

Parameter	*Day 21 pretreatment cycle*	*Day 21 treatment cycle*
GEST		
Free fraction (%)	1.37 ± 0.31	0.81 ± 0.15
SHBG-bound (%)	66.5 ± 6.9	76.6 ± 5.8
Albumin-bound (%)	32.2 ± 6.6	22.6 ± 5.8
SHBG (nmol/L)	90.3 ± 36.0	198.8 ± 52.0
CBG (μg/ml)	37.4 ± 5.2	84.9 ± 11.4

Table V. Pharmacokinetic parameters of GEST (mean ± SD) obtained by model-fitting based on total and free concentrations in serum of 10 women (on day 21 of treatment) who received the triphasic preparation during one cycle

Parameter	*Total GEST*	*Free GEST*
C_{max} (ng/ml)	18.2 ± 4.5	0.15 ± 0.04
t_{max} (hr)	0.8 ± 0.4	0.9 ± 0.4
AUC (0-24 hr) (ng · ml^{-1} · hr)	226.6 ± 77.1	1.8 ± 0.6
AUC (ng · ml^{-1} · hr)	422.6 ± 178.5	3.5 ± 1.5
$t_{1/2}$ (hr)	22.0 ± 4.1	22.9 ± 5.4

was determined to 1.37% ± 0.31% and the fraction bound to SHBG and albumin was 66.5% ± 6.9% and 32.2% ± 6.6%, respectively. CBG concentrations in the serum were 37.4 ± 5.2 μg/ml; SHBG concentrations were 90.3 ± 36.0 nmol/L (Table IV). The free concentrations of GEST were used to calculate the pharmacokinetic parameters of free GEST by model-fitting (Table III).

A computer simulation of GEST trough levels in the serum during a complete treatment cycle of 21 days was performed on the basis of the data obtained after single-dose administration on day 21 of the pretreatment cycle (Fig. 3) except that the terminal half-life was set to a value of 22 hours, which represented the experimentally observed value at the end of one treatment cycle in the second part of study II. Both curves showed similar time course except that the experimentally determined trough levels of GEST, which reached a steady state on approximately day 16, increased more markedly and reached a considerably higher plateau in the last week of treatment compared with the simulated trough levels. An accumulation factor (R) of 1.9 can be calculated from a terminal half-life of 22 hours and a dosing interval of 24 hours. Values calculated for R* and R** were 2.3 and 3.4, respectively. Corresponding values of R* and R** for the free GEST were 1.3 and 1.9, respectively.

Study II: Pharmacokinetics of GEST after multiple-dose administration to white women. Mean trough concentrations of GEST increased during the treatment cycle and reached a steady state on about day 16 (Fig. 3). On the last day of treatment (day 21), maximum concentrations of GEST in the serum were observed 0.8 ± 0.4 hour after administration and amounted to 18.2 ± 4.5 ng/ml. The terminal half-life of disposition was 22.0 ± 4.1 hours. The AUC (0 to 24 hours) was 226.6 ± 77.1 ng * hr * ml^{-1}; corresponding AUC value was 422.6 ± 178.5 ng * hr * ml^{-1}.

The corresponding pharmacokinetic parameters calculated from the free GEST concentrations in serum are also presented (Table V).

The free fraction of GEST was determined in the serum samples obtained throughout the treatment cycle. During treatment free GEST fractions decreased from a pretreatment value of 1.37% ± 0.31% to a value of 0.81% ± 0.15% on day 21 of treatment. The fractions of GEST bound to SHBG and albumin were 76.6% ± 5.8% and 22.6% ± 5.8%. The mean SHBG and CBG levels on day 21 were 198.8 ± 52.0 nmol/L and 84.9 ± 11.4 μg/ml, respectively (Table IV).

SHBG concentrations showed a steady increase in 8 of 10 women throughout treatment and were correlated significantly with the corresponding GEST concentrations in serum (Fig. 4). In two women relatively high SHBG concentrations were already observed when treatment started, and they remained nearly unchanged throughout treatment. The correlation coefficients for total and free GEST concentrations, respectively, and the corresponding SHBG levels were calculated individually, and for eight women were in the range of 0.7101 and 0.9112 (mean, 0.8195) and 0.5553 and 0.9126 (mean, 0.7914), respectively. In two women there was no correlation between both parameters.

Comment

Two different triphasic oral contraceptives were investigated, one containing LNG and the other GEST as progestagenic compound. However, the studies were carried out in two different ethnic populations and with slightly different design, since they were performed independent of each other and not particularly for comparative purposes. Nevertheless, it became obvious that both progestins, when administered in combination with EE_2 as triphasic formulations, showed very similar concentration profiles during a treatment cycle.

Pharmacokinetic parameters of LNG obtained after the administration of a single oral dose to Japanese women were in good accordance with published data on single dose administration in white subjects,[1] although somewhat higher drug levels were found in the plasma of Japanese women because of their comparatively lower body weight. Because terminal half-life

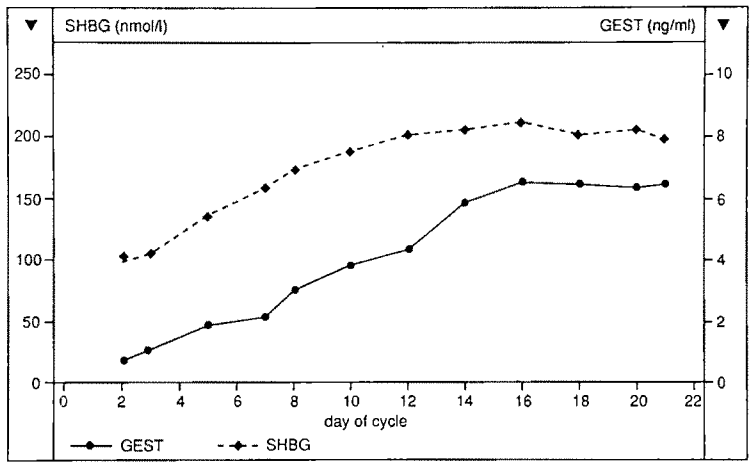

Fig. 4. Mean serum levels of SHBG and GEST in 10 white women during one treatment cycle.

estimation was based on 8 and 24 hour values only, the half-life of LNG was somewhat shorter than reported previously.[5] The pharmacokinetic parameters of LNG obtained with and without the use of model-fitting were identical, thus proving the validity of the model. During 1 month of treatment with the triphasic preparation, plasma trough levels of LNG increased concomitantly with the increasing dose of LNG administered and reached a steady state on about day 16 of treatment. Simulated trough levels of LNG showed a similar time course, although the rise was less steep and the steady state reached was considerably lower compared with experimentally determined values. Computer simulation assumed linear pharmacokinetics of LNG during long-term administration and any deviation of experimentally determined trough levels from the simulated ones indicated additional influences on the drug's disposition, which were due to long-term treatment and did not occur during single-dose administration. At least two different factors, which may affect the drug's distribution and disposition from plasma, have been reported for contraceptive steroids; one is an impairment of hepatic metabolic capacity, whereas the other relates to changes in protein binding. There have been numerous reports on impairment of hepatic drug-metabolizing enzymes in women under oral contraceptive therapy.[11-13]

This was true for formulations containing LNG and other progestins, and although GEST in particular was not yet investigated, it can be assumed that it also follows the general line. For steroids such as LNG and GEST, which are characterized by a restrictive hepatic elimination, any impairment of the metabolic capacity during long-term treatment could lead to higher drug levels in the plasma than anticipated from single-dose pharmacokinetics. On the other hand, it is well known that concomitant administration of EE_2 can increase SHBG concentration throughout treatment, and because LNG and GEST bind with a high affinity to SHBG, an increase in total drug levels in the serum is the result. Although SHBG was not determined in the present study with Triquilar, most published information on this particular triphasic formulation indicates about a 100% increase in SHBG levels during a treatment cycle,[14-16] although a smaller increase has been reported as well.[17]

Because computer simulation did not account for any changes in hepatic metabolic capacity or in plasma protein binding during treatment, a comparison of simulated and experimentally obtained trough level curves allowed an estimation of the relative contribution of both factors to the observed increase in LNG concentrations in plasma. Therefore a ratio of 2.9 for the two steady-state concentrations indicated about threefold higher LNG concentrations during treatment than anticipated on the basis of single-dose pharmacokinetics alone.

Similarly, when the ratio of the AUC obtained after single-dose administration and the AUC of one dosing interval on day 21 of the treatment cycle was examined, fourfold higher drug levels were found during treatment. Thus the relative contribution of factors other than the relationship of terminal half-life and dosing interval to the total accumulation of LNG in the plasma was about 75%.

A very similar observation was made with GEST. Data obtained from single-dose administration to white women were in good agreement with those observed in previous studies (Kuhnz W, et al. Unpublished data). However, compared with a previously performed study on single-dose administration of a GEST-containing formulation, a slightly different protein binding pattern of GEST was observed in the present study. Compared with the former study, in the present study, higher SHBG concentrations and a higher proportion of GEST bound to SHBG were found in the serum.

and a smaller fraction of GEST unbound was observed.

The most likely explanation for this phenomenon is that only women who had not previously taken any oral contraceptives were included in the previously performed study, whereas in the present study most women were regularly taking oral contraceptives and only stopped taking the pill between 2 and 6 months before the study started. The administration of GEST over a whole treatment cycle resulted in increasing trough levels, which reflected the triphasic pattern of the GEST doses administered. The increasing trough levels were paralleled by a 2.2-fold increase in SHBG concentrations in serum, and a close correlation between both parameters was found in 8 of 10 women. However, two women showed no such correlation; they already had high pretreatment levels of SHBG that decreased slightly during treatment, although GEST concentrations increased in a similar way as in the other women. A very similar observation has been reported previously on LNG,[18] in which seven of nine subjects had a close positive correlation between SHBG and LNG levels, whereas two other women had no such correlation. Both women already started with high SHBG levels, which decreased during treatment. In the present study a comparison with experimentally observed steady-state concentrations revealed 2.3-fold higher GEST concentrations during treatment than those calculated on the basis of single dose pharmacokinetics.

Likewise, an evaluation of the AUCs revealed 3.4-fold higher drug levels during treatment. Therefore the relative contribution of serum protein binding and hepatic metabolic impairment to the total concentration of GEST in serum at steady state was about 71%.

When free GEST concentrations were considered in the same way, only 1.3-fold and 1.9-fold higher drug levels were calculated. Although this was still somewhat higher than unity, it clearly demonstrated the influence of protein binding for the observed increase in GEST trough levels in serum. For restrictively cleared drugs such as LNG and GEST, an increase in serum protein binding affects not only volume of distribution and thus drug levels in serum, but also the progestin's terminal half-life. Because of the relative increase in the SHBG-bound fraction of the progestin, which is not readily metabolized by the liver, the drug's terminal half-life will be prolonged, which in fact was observed with GEST.

Both increasing progestin levels and prolonged terminal half-lives could also be explained by an impairment of hepatic metabolism. However, where there is evidence for the contribution of protein binding, it remains unclear whether metabolic impairment plays an important role.

In conclusion, it became apparent that the pharmacokinetic parameters obtained after single-dose administration of either of the two progestins cannot be used to predict their pharmacokinetic behavior completely during a treatment cycle; the main reason is the continuously altered protein binding of the progestins because of EE_2-induced SHBG synthesis.

However, single-dose pharmacokinetics of a progestin, together with computer simulation based on pharmacokinetic modeling, can be a useful tool to detect any deviations from linear pharmacokinetics during repeated administration. Along with additional information, for example, on altered binding capacity of SHBG, the interpretation of experimentally obtained results is greatly facilitated.

Pharmacologic and pharmacokinetic characteristics of norgestimate and its metabolites

John L. McGuire, PhD, Audrey Phillips, PhD, DoWon Hahn, PhD, Edward L. Tolman, PhD, Soledad Flor, PhD, and Michael Edwin Kafrissen, MD, MSPH
Raritan, New Jersey

Biotransformation, pharmacologic, and pharmacokinetic studies of norgestimate and its metabolites indicate that 17-deacetyl norgestimate, along with the parent drug, contributes to the biologic response. The postulated metabolic pathway, which is based on the identification of urinary products had indicated that three metabolites of norgestimate, 17-deacetyl norgestimate, 3-keto norgestimate, and levonorgestrel, might participate in the response. The pharmacologic evaluation of these metabolites demonstrates that only 17-deacetyl norgestimate has a pharmacologic profile consistent with that of norgestimate, and significant concentrations of this metabolite have been measured in the serum of women after the administration of norgestimate. These studies indicate that 17-deacetyl norgestimate contributes to the pharmacologic response to norgestimate. (Am J Obstet Gynecol 1990;163:2127-31.)

Key words: Norgestimate, norgestimate metabolites, 17-deacetyl norgestimate

Norgestimate is a progestin used in combination with ethinyl estradiol as an oral contraceptive. Because some steroids exert their pharmacologic effects through active metabolites, in addition to the parent drug, we have investigated whether the pharmacologic activity of norgestimate (Fig. 1) might be mediated, at least in part, through any of its metabolites. Biotransformation studies have been conducted to examine the metabolism of norgestimate; the pharmacologic profiles of three metabolites have been compared with that of norgestimate, and the pharmacokinetics of norgestimate and 17-deacetyl norgestimate, a metabolite believed to contribute significantly to the biologic response, have been examined. In this article the results of these studies are reviewed, with emphasis placed on how they contribute to our further understanding of norgestimate's action.

Pharmacokinetics and biotransformation

The pharmacokinetics of ^{14}C-norgestimate have been studied in several animal species and appear to be consistent with those of other contraceptive progestins.[1] In rats, dogs, and monkeys, orally administered ^{14}C-norgestimate is rapidly absorbed, with peak levels of radioactivity achieved within 4 hours of administration, and it is eliminated with a half-life that ranges from 30 to 67 hours. After oral administration to women, ^{14}C-norgestimate is rapidly absorbed, with peak levels of radioactivity ranging from 30 minutes to 2 hours, and

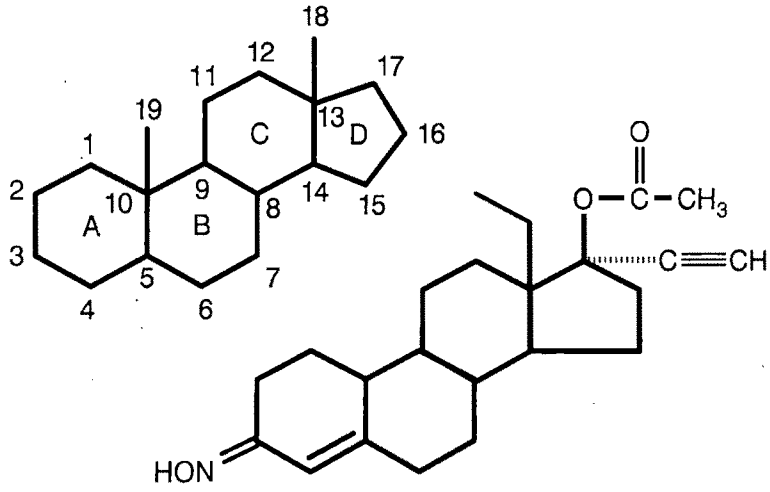

Fig. 1. Structure of norgestimate and steroid nucleus.

it is eliminated with a half-life ranging from 45 to 71 hours.[2]

The biotransformation of norgestimate in women has been investigated by identifying urinary metabolites after the oral administration of ^{14}C-norgestimate.[3] As in studies of other steroids, the identification and quantification of terminal norgestimate metabolites represent a sampling, depending on the availability of reference standards. Although these metabolites and their amounts do not necessarily reflect the total metabolite profile or their contribution to the biologic response, the chemical structures of identified urinary metabolites provide a basis to postulate the major metabolic pathways. After extraction and chromatographic separation, five 17α-ethinyl metabolites or norgestimate have been identified by gas chromatography–mass spectrometry and by comparison with several available reference standards.[3] The chemical structures of these terminal metabolites indicate that in women, norgestimate undergoes metabolism involving hydrolysis at position 17, cleavage of the oxime and subsequent reduction of the ketone at position 3, hydroxylation in the A and D rings, reduction of the double bond at C_4-C_5, and subsequent conjugation to a glucuronide or sulfate. Urinary metabolites identified in analogous studies that use ^{14}C-norgestimate in rats, dogs, and monkeys suggest that metabolic pathways in these species are similar to those in women. These studies indicate the possibility that 17-deacetyl norgestimate, 3-keto norgestimate, and 17-deacetyl–3-keto norgestimate (levonorgestrel) might contribute to the pharmacologic response observed after oral administration of norgestimate to women. To examine this possibility further, we have investigated the pharmacologic profiles of these metabolites and have compared them with that of norgestimate.

Pharmacologic evaluation of norgestimate, 17-deacetyl norgestimate, 3-keto norgestimate, and levonorgestrel

Laboratory studies. The pharmacology of norgestimate, which has been studied extensively and reported previously,[4-8] is summarized here briefly. The affinity of norgestimate for rabbit uterine cytosolic progestin receptors in vitro is similar to that of progesterone. The stability of norgestimate throughout the incubation period in the receptor-binding studies has been monitored, confirming the affinity of unchanged norgestimate for progestin receptors.[6] Additional evidence of norgestimate's inherent progestational activity is provided by experiments that show its local stimulation of the rabbit endometrium when injected directly into the uterine lumen[6] and its ability to directly inhibit luteinizing hormone–releasing hormone–stimulated luteinizing hormone release from rat pituitary cells in vitro.[8]

In conventional endocrine bioassays, norgestimate exhibits activity characteristic of a progestin. It stimulates the endometrium after oral administration to estrogen-primed immature rabbits.[5] In this test system the potency of norgestimate is maintained after subcutaneous administration (0.24 and 0.34 times that of levonorgestrel after oral and subcutaneous administration, respectively) which shows that the progestational action of norgestimate is not dependent on first-pass oral metabolism. Norgestimate, like progesterone, also maintains pregnancy in ovariectomized rats and effectively inhibits ovulation in several species.

The relative lack of androgenicity of norgestimate is shown by its very weak affinity for rat prostatic androgen receptors (relative binding affinity of 0.003 times that of dihydrotestosterone), its ability to stimulate ventral prostate growth in immature castrated rats only to the same degree as progesterone (relative potency of

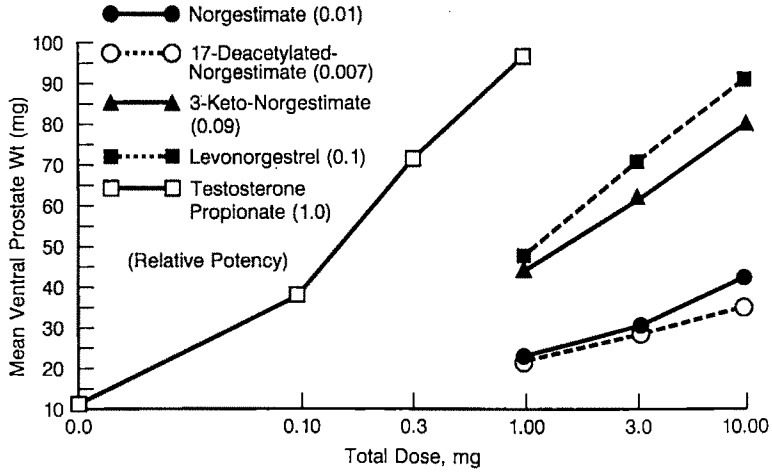

Fig. 2. Stimulation of ventral prostate growth after administration to immature castrated rats. (Relative potency estimates from Phillips et al.[6])

0.003 to 0.03 times that of testosterone),[6] and its virtual lack of affinity for human sex hormone–binding globulin (SHBG) in vitro (inhibiting concentration of 50% [IC_{50}] > 10,000 nmol/L).[7]

To determine whether 17-deacetyl norgestimate, 3-keto-norgestimate, or levonorgestrel contributes to the pharmacologic activity of the parent drug, these steroids were tested in the same assays described above. If any of these metabolites contribute significantly to the pharmacologic activity of norgestimate, their pharmacologic activity profile would be consistent with that observed after the administration of norgestimate.

17-Deacetyl norgestimate, 3-keto norgestimate, and levonorgestrel demonstrate affinity for progestin receptors by displacing ^{3}H-R5020 from rabbit uterine receptors with relative binding affinities of 0.94, 5.21, and 5.41 times that of progesterone, respectively.[6] These steroids also stimulate the endometrium of estrogen-primed immature rabbits with relative potencies of 1.4, 3.4, and 4.9 times that of norgestimate, respectively.[6] Therefore each of these three steroids show progestational activity. However, to evaluate whether they might act as biologically active metabolites of norgestimate, it was necessary to also assess their androgenicity, because a lack of androgen-related pharmacology is a characteristic or norgestimate.

Comparative laboratory assays show that levonorgestrel and 3-keto norgestimate have a pharmacologic profile different from that of norgestimate. Therefore it appears unlikely that either of these steroids contributes significantly to the pharmacologic response of norgestimate. In contrast to norgestimate, levonorgestrel has significant affinity for androgen receptors in vitro (relative binding affinity of 0.22 times that of dihydrotestosterone),[6] significant stimulation of prostate growth in rats (relative potency of about 0.1 times that of testosterone; Fig. 2),[6] and significant affinity for human SHBG in vitro (IC_{50} = 53.4 nmol/L).[7] 3-Keto norgestimate also appears to be significantly androgenic, though less so than levonorgestrel. The relative binding affinity of 3-keto norgestimate for rat androgenic receptors is 0.025 times that of dihydrotestosterone; its potency in stimulating prostate growth in rats is equal to that of levonorgestrel (Fig. 2), but this progestin exhibits no affinity for human SHBG in vitro (IC_{50} > 10,000 nmol/L).

In contrast to levonorgestrel and 3-keto norgestimate, 17-deacetyl norgestimate, like norgestimate, has little or no activity in each of the three androgenic test models. Its relative binding affinity for rat androgen receptors is only 0.013 times that of dihydrotestosterone; whereas its ability to stimulate prostate growth in rats is similar to that of norgestimate (Fig. 2). Finally, it shows a lack of affinity for human SHBG in vitro (IC_{50} > 10,000 nmol/L).

These data suggest that it is unlikely that either levonorgestrel or 3-keto norgestimate contributes significantly to the pharmacologic activity of norgestimate, since the androgenicity of these compounds is inconsistent with the pharmacologic profile of norgestimate. However, the pharmacologic profile of 17-deacetyl norgestimate is similar to that of norgestimate, which suggests that it may be an important contributing metabolite.

Clinical studies. Based on the results of preclinical studies, norgestimate and 17-deacetyl norgestimate should have minimal effect on ethinyl estradiol–induced elevations in circulating levels of SHBG and high-density lipoprotein (HDL), whereas levonorgestrel and 3-keto norgestimate should significantly reduce these levels. This prediction has been based on the sensitivity of these levels to androgenic stimulation. SHBG levels in women during combined oral contraceptive use are considered a measurement of the relative es-

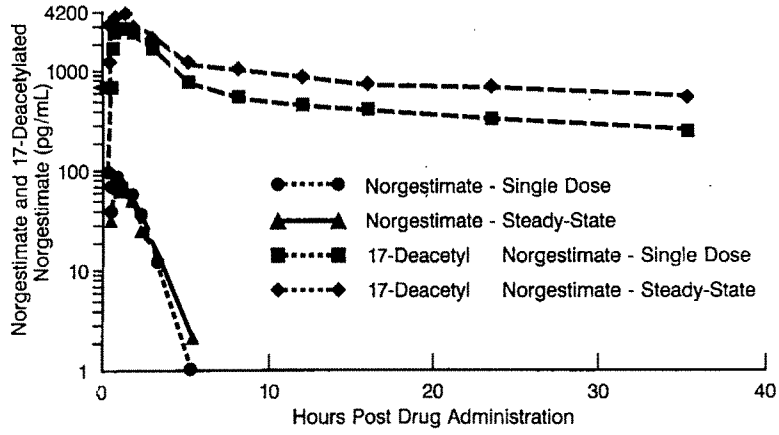

Fig. 3. Mean serum levels of norgestimate and 17-deacetyl norgestimate after single- and multiple-dose administration of 360 μg of gestimate to 10 human female subjects.

trogen and androgen activities of the combined product, since estrogens elevate and androgens lower SHBG levels.[9,10] Another androgen-sensitive parameter is lipid levels. It has been shown that estrogens elevate HDL levels whereas androgens have the opposite effect.[11-13]

Two of the progestins, norgestimate and levonorgestrel, are used in combination with ethinyl estradiol as oral contraceptives and have been compared for their effects of SHBG and HDL levels. In a study of 40 women after four treatment cycles, norgestimate does not appreciably inhibit estrogen-induced elevations in SHBG levels (161.2% change from pretreatment levels after norgestimate : ethinyl estradiol, 250 : 35 μg).[14] However, the relatively lower SHBG levels in women treated with the levonorgestrel product (26.2% change from pretreatment after levonorgestrel : ethinyl estradiol, 150 : 30 μg) indicate that levonorgestrel has markedly reduced the elevation in SHBG levels resulting from ethinyl estradiol. In a large multicenter study of these same two oral contraceptives in more than 1000 women, significant elevations in HDL levels were observed after 3, 6, 12, and 24 cycles of treatment with the norgestimate–ethinyl estradiol product (8.8% maximum increase), which is in contrast to the significant decrease in HDL levels observed during these same cycles of treatment with the levonorgestrel product (7.6% maximum decrease).[14]

These clinical data and the laboratory data demonstrate very different profiles for norgestimate and levonorgestrel, suggesting that levonorgestrel does not appear to make an important contribution to the pharmacologic activity of norgestimate.

Pharmacokinetics of norgestimate and 17-deacetyl norgestimate

The pharmacologic evaluation of norgestimate's metabolites has suggested that 17-deacetyl norgestimate might contribute to the response. Studies by Madden and Back (see this Supplement) demonstrate that 17-deacetyl norgestimate is the major metabolic product of norgestimate in human intestinal and hepatic tissues in vitro.

A recent study in our laboratory that characterized the pharmacokinetics of norgestimate and 17-deacetyl norgestimate in the serum of women after norgestimate administration is consistent with the significant contribution of this metabolite to the response to norgestimate. In this study, 10 healthy women have received single (day 1) and multiple doses (days 4 to 10) of two identical tablets, each containing 0.180 mg of norgestimate and 0.035 mg of ethinyl estradiol (the norgestimate clinical dose is 0.250 mg daily). Intensive blood sampling has been performed after the first and last doses. Serum concentrations of norgestimate and 17-deacetyl norgestimate have been measured by high-pressure liquid chromatography–radioimmunoassay procedures (unpublished data). Norgestimate is rapidly absorbed from the tablets. Mean peak norgestimate concentrations of 100 pg/ml are observed within 1 hour of administration, both after single dose and at steady state (Fig. 3), followed by a rapid decline caused by distribution and elimination. Norgestimate concentrations after single- or multiple-dose administration are generally below assay detection within 5 hours after dosing, which precludes an accurate determination of its elimination half-life.

Consistent with the in vitro studies in human intestinal and hepatic tissues, the metabolite 17-deacetyl norgestimate appears rapidly in serum after single and multiple norgestimate doses, with concentrations greatly exceeding those of norgestimate (Fig. 3). Mean peak concentrations of 3597 and 4436 pg/ml are observed at 1.5 and 1.4 hours after single dose and at steady state, respectively, which indicates that there is a rapid and substantial conversion of norgestimate to 17-deacetyl norgestimate after oral administration of

norgestimate. A certain degree of accumulation of the 17-deacetyl norgestimate is observed after multiple dosing, as would be anticipated from its estimated half-life of 16 to 17 hours.

Comment

Significant progress has been made in understanding the contribution of metabolites to the response to norgestimate. However, additional studies are needed. Other metabolites need to be identified, but it is important to point out that relatively few metabolites have been identified for any steroid to date and that such work is painstakingly difficult and time consuming. Blood levels of other metabolites also need to be determined. However, because some of these metabolites bind strongly to SHBG in serum and SHBG is significantly elevated in women using norgestimate–ethinyl estradiol, the measurements of these metabolites and the relationship of such measurements to their contribution to the response are complicated.

The studies reported here indicate that 17-deacetyl norgestimate, together with the parent drug, contributes significantly to the response to norgestimate. Significant blood levels of this metabolite have been demonstrated in women after norgestimate administration, and its pharmacology is consistent with that of norgestimate.

Serum pharmacokinetics of orally administered desogestrel and binding of contraceptive progestogens to sex hormone–binding globulin

Willem Bergink, PhD,[a] Roel Assendorp, MSc,[a] Lenus Kloosterboer, PhD,[a] Wim van Lier, MSc,[a] Gerrit Voortman, MSc,[a] and Ingelise Qvist, MD[b]

Oss, The Netherlands, and Horsens, Denmark

Serum levels of 3-ketodesogestrel and ethinyl estradiol were analyzed by radioimmunoassay in a balanced crossover study with two tablet formulations containing desogestrel (0.150 mg) and ethinyl estradiol (0.030 mg) in 25 women under steady-state conditions after 21 days of treatment. The pharmacokinetic properties of desogestrel were characterized by the following parameters: (1) maximum serum concentration, (2) time to maximum serum concentration, (3) total area under the serum concentration versus time curve, and (4) serum half-life of elimination. The interindividual variation in these parameters was comparable with that observed with other contraceptive combinations containing ethinyl estradiol and norethisterone, levonorgestrel, or gestodene. The serum distribution of contraceptive progestogens is known to be determined by their affinity to sex hormone–binding globulin and the concentration of sex hormone–binding globulin. We analyzed the structural features that determine binding to sex hormone–binding globulin. The 13-methyl group increased and the 11-methylene group weakened the binding to sex hormone–binding globulin. The double bond at C-15 reinforced the binding only when combined with an 18-methyl group. Therefore, the binding of levonorgestrel (the 18-methyl derivative of norethisterone) and gestodene (the Δ-15,18 methyl derivative of norethisterone) to sex hormone–binding globulin was much stronger than that of 3-keto-desogestrel and norethisterone. (AM J OBSTET GYNECOL 1990;163:2132-7.)

Key words: Desogestrel, oral contraceptive, pharmacokinetics, sex hormone–binding globulin

The pharmacokinetics and metabolism of contraceptive progestogens and ethinyl estradiol (EE) have been analyzed in several studies,[1-7] and considerable variation was observed in the pharmacokinetic parameters. Only a few studies are adequate for a meaningful comparison of the rate and the extent of absorption and the rate of elimination, because in many studies data have been obtained with only a limited number of volunteers.

Parameters that are characteristic for the pharmacokinetic properties of the hormonal components in an oral contraceptive tablet, namely, maximal serum concentration (C_{max}), time to maximum serum concentration (T_{max}), area under the serum concentration versus time curve (AUC), and serum elimination half life ($T_{1/2}el$), are subject to several factors, which influence the variability. These factors result not only in considerable interindividual variation,[2,7] but also in intercenter variation in the pharmacokinetic parameters.

Relevant to this aspect may be variations in environmental factors, patient characteristics, assay methods, and the first-pass effect. The latter was reported as specifically relevant to plasma level variability.[8]

It has also been concluded that levonorgestrel and gestodene are 80% to 100% bioavailable and therefore have no or a limited first-pass effect.[9,10] The bioavailability of other compounds (e.g., norethisterone, EE, and desogestrel) has been reported to be less. Therefore in the present study we analyzed the interindividual variability of the mean values of the pharmacokinetic parameters (C_{max}, t_{max}, AUC, and $t_{1/2}el$) for orally administered desogestrel in comparison with the values found in other studies with oral contraceptives containing EE and desogestrel, EE and levonorgestrel, EE and norethisterone, and EE and gestodene.

In addition to presystemic metabolism (i.e., absorption by the gut wall and first-pass metabolism in the liver), the plasma levels of contraceptive steroids strongly depend on binding to plasma proteins. A close correlation between plasma concentrations of levonorgestrel or norethisterone and sex hormone–binding globulin (SHBG) binding capacity as found by Victor and Johansson[11] and Back et al.[12] indicates the importance of SHBG binding for the pharmacokinetics of

contraceptive progestogens. Therefore we have also analzyed the binding affinity of contraceptive progestogens to SHBG.

Material and methods

Estimation of SHBG binding capacity. The SHBG binding capacity has been estimated with the dextran-coated charcoal method for the separation of bound and free steroid as described by Hammond and Lähteenmäki.[13] The binding was determined in the presence of cortisol (200 nmol/L) to prevent binding to transcortin-binding sites. Human serum was diluted (dilution factor 26) with a 0.25% dextran-coated charcoal, 0.025% dextran T70 suspension in buffer (10 mmol/L TRIS, 5 mmol/L $CaCl_2$, glycerol 0.3 mol/L, pH 7.4) and incubated for 30 minutes at room temperature to remove endogenous steroids. The mixture was centrifuged (15,000 N/kg for 10 minutes), and the stripped serum was used for the determination of the relative binding affinities of progestogens to SHBG.

The relative binding affinities were estimated with a 3-point parallel line assay.[14] To determine relative affinity, 0.100 ml of stripped serum and 0.100 ml of a saturating concentration of labeled 5α-dihydrotestosterone and increasing concentrations of unlabeled progestogens were incubated for 30 minutes at 37° C. Nonspecific binding was measured in the presence of 100 nmol/L of unlabeled 5α-dihydrotestosterone. The results of several tests were combined according to the procedure described in the *United States Pharmacopeia.*[15]

Estimation of pharmacokinetic parameters for EE and desogestrel. The preparations were as follows: (1) a tablet with a diameter of 6 mm, containing 0.150 mg of desogestrel + 0.030 mg of EE and (2) a smaller tablet with a diameter of 5 mm, which also contained 0.150 mg of desogestrel + 0.030 mg of EE.

Volunteers. Twenty-five healthy female volunteers, ages 20 to 29 years, who voluntarily gave written informed consent, participated in this study. The subjects were accurate with respect to tablet intake, had a cycle length around 28 days (28 ± 2 days), and had less than three abnormal-linked laboratory values during biochemical and hematologic screening before treatment.

The subjects also fulfilled the following criteria: (1) women were excluded during 3 months after a partus, an abortion, or stopping breast-feeding; (2) women should not be heavy smokers (> four cigarettes daily), heavy drinkers (not more than five glasses per week and no alcohol was taken within 3 days before an assessment day), or overweight (< ideal weight + 20%); (3) women should not have been treated with oral contraceptives or other hormonal preparations within a 2-month period before the start of the study or treated with an implant or injectable contraceptive within the previous 6 months were excluded. Moreover, women with a poor physical condition, abnormal fasting glucose levels, a history of gestational diabetes, a history or a family history of diabetes mellitus, and diseases known to be associated with lipid disorders were also excluded. Special attention was also given to the general exclusion criteria (thromboembolic disease, known or suspected estrogen-dependent tumors, etc.). Finally, subjects did not take rifampicin, tetracycline, phenylhydantoin, and phenobarbital during the 2 months before the start of treatment and during treatment.

5α-DHT, 5α-Dihydrotestosterone; *NET,* norethisterone.
*Results of three tests were combined.

Design. The volunteers were randomly divided over two groups. Group I consisted of 11 volunteers and group II consisted of 14 volunteers.

Group I started with the 6 mm tablet and group II started with the 5 mm tablet in the first treatment cycle.

After 21 days of treatment a tablet-free period of 7 days followed, after which the treatments were reversed. Group I then received the 5 mm tablet for 21 days and group II received the 6 mm tablet for 21 days.

Blood sampling scheme. Just before and after the twenty-first dose, blood samples were taken for 3-ketodesogestrel and EE determinations. Sampling on day 21 started at 8:00 AM, just before the intake of tablet 21. The day before sampling, no food was taken after 8:00 PM. The samples were taken at the following times: 0 (just before intake), 0.5, 1, 1.5, 2, 2.5, 3, 4, 5, 6, 8, 12, 16, 24, 48 and 72 hours after intake of the tablet.

Blood was allowed to clot at room temperature for 30 minutes and then centrifuged at 2.5 × 10^4 N/kg for 10 minutes at 4° C. Serum was collected, frozen, and stored at −20° C until analysis.

EE and 3-ketodesogestrel assay. EE concentrations were estimated by a specific radioimmunoassay using 17α-[6,7-^{3}H]-EE (New England Nuclear) as tracer, specific activity 2200 gigabecquerel (GBq)/mmol, and anti-serum raised in rabbits against EE-3-succinyl–bovine serum albumin. The working dilution of the antiserum was 1/16000. The detection was accurate

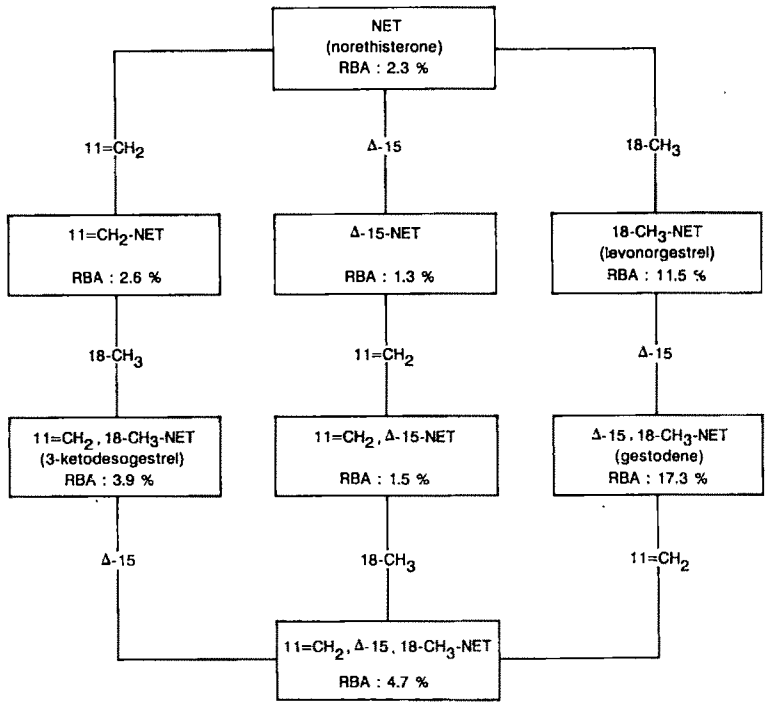

Fig. 1. Relative binding affinities *(RBAs)* of progestogens derived from norethisterone to SHBG.

with variation coefficients of <25% over the range of 20% to 80% relative binding of ligand to antibody. The sensitivity of this radioimmunoassay approximated 150 fmol/ml at 50% relative binding and 65 fmol/ml at 80% relative binding. Therefore sensitivity was sufficient for the detection of serum values of EE up to at least three elimination half-lives, namely, 180 and 100 fmol/ml were detected 48 and 72 hours, respectively, after intake of the last tablet.

3-Ketodesogestrel concentrations were estimated by a radioimmunoassay using [16,^{3}H]3-ketodesogestrel (Organon) as tracer, specific activity 1702 GBq/mmol, and antiserum raised in rabbits against 3-ketodesogestrel-3-(0-carboxymethyl)oxime–bovine serum albumin. The working dilution of the antiserum was 1/50000. Cross-reacting metabolites did not interfere, because they are not believed to be present in serum in measurable amounts after desogestrel treatment.[16] The sensitivity of this radioimmunoassay approximated 300 fmol/ml at 50% relative binding of ligand to antibody. This sensitivity was sufficient to detect the serum levels of 3-ketodesogestrel 48 and 72 hours after intake of the last tablet, namely, 1300 and 700 fmol/ml, respectively.

For both methods, before assay the samples were extracted with 3 ml "Baker SPE octadecyl (C18)" disposable columns. SAC-CEL (Wellcome Diagnostics), donkey antirabbit antiserum coupled with cellulose, was used to perform bound/free ligand separation.

Pharmacokinetic calculations. The following pharmacokinetic parameters were calculated from the 3-ketodesogestrel serum levels:

1. C_{max} and t_{max} were taken from the measured serum level data.
2. Elimination half-life ($t_{1/2}$el): by means of the individual plots of the log-concentration versus time, it was established from which time onward up to the last time the curve was approximately log-linear.
3. Using log-linear regression on these terminal data points, the elimination half-life for each individual subject was estimated.
4. AUC_0: The $AUC_{0\text{-}24}$ (= AUC of one dosing interval) was calculated by means of the linear trapezoidal rule.

Results and comment

Binding of contraceptive progestogens to SHBG. The pharmacokinetics of contraceptive progestogens are known to be influenced by the binding to SHBG. During multiple dosing of OCs containing EE and norethisterone, levonorgestrel, gestodene,[17] or desogestrel,[18] a progressive rise in the serum concentration of these progestogens or their active metabolite was found, which was correlated with the rise in SHBG.[11, 12, 17, 19] All the progestogens are bound to a variable degree to SHBG[1] as a result of a variation in their affinity to SHBG. In the present study we have estimated the binding affinities of the progestogens derived from norethisterone. Table I shows the relative

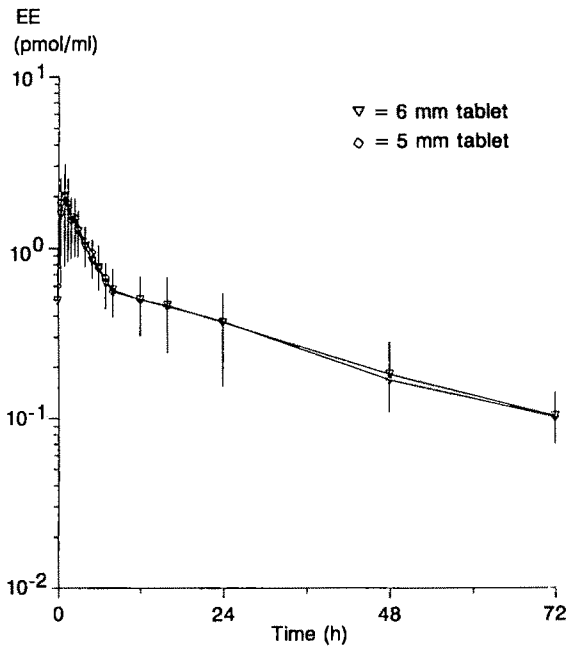

Fig. 2. Serum concentration of EE after the administration of two tablet formulations containing 0.150 mg of desogestrel and 0.030 mg of EE in 25 women on day 21 of the treatment cycle.

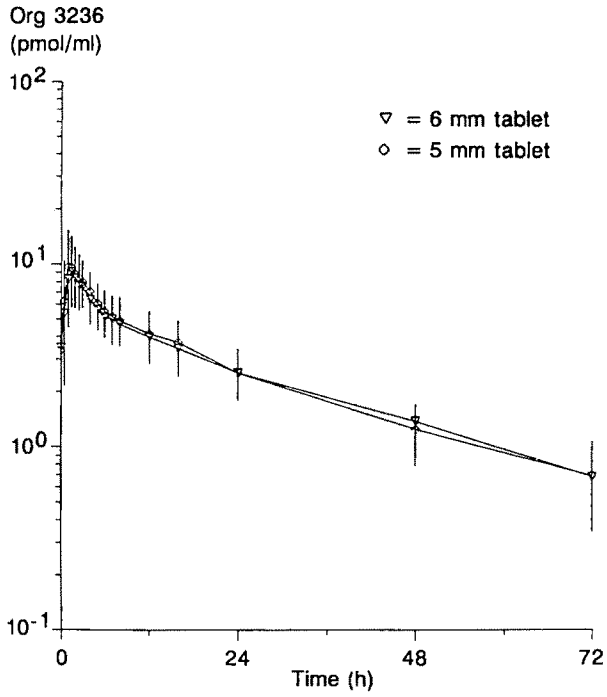

Fig. 3. Serum concentration of 3-ketodesogestrel after the administration of two tablet formulations containing 0.150 mg of desogestrel and 0.030 mg of EE in 25 women on day 21 of the treatment cycle.

binding affinities of norethisterone and the seven possible derivatives of norethisterone containing 18-methyl, 11-methylene, or Δ-15 substituents alone or combinations of these substituents. Norethisterone, levonorgestrel (18-methyl derivative), 3-ketodesogestrel (11-methylene, 18-methyl derivative), and gestodene (Δ-15, 18-methyl derivative) are presently used for contraceptive purpose. Norethisterone displays weak binding (relative binding affinity = 2.3%). The introduction of a 18-methyl group in norethisterone results in a significant increase in binding affinity (the relative binding affinity of levonorgestrel is 11.5%, as was found previously[16]), whereas the 11-methylene group and the double bond at position C-15 had no effect or resulted in a significant decrease, respectively. However, the introduction of the double bond at position C-15 (Δ-15 substitution) in levonorgestrel resulted in a further increase. The relative binding affinity of gestodene (17.3%) was only slightly less than that of testosterone (22%). The combination of the 11-methylene group and the 18-methyl group (3-ketodesogestrel) displayed a weak binding as did the combination of the double bond at position C-15 and the methylene group at C-11 (11-methylene, Δ-15-norethisterone). The compound with all three possible modifications had a weak binding to SHBG. The influence of all these modifications of the norethisterone molecule is schematically represented in Fig. 1.

Pharmacokinetics of desogestrel (0.150 mg) and EE (0.030 mg) in tablets under steady-state conditions. In the present study we have estimated serum EE and serum 3-ketodesogestrel concentrations in 25 women in a crossover bioequivalence study with two types of tablets containing 0.030 mg of EE and 0.150 mg of desogestrel, which were taken for 21 days. Volunteers were divided into two groups. One group started with the smaller tablet (5 mm), whereas the other group took the larger 6 mm tablet. Treatment was reversed after 21 days of treatment and a tablet-free period of 7 days. Blood samples were taken just before and after the last tablet of each treatment cycle (day 21) for the estimation of EE and 3-ketodesogestrel. The results demonstrated complete bioequivalence for both tablets.

Mean plasma EE and 3-ketodesogestrel concentrations after intake of both tablets at day 21 of the treatment cycles are shown in Figs. 2 and 3, respectively. The ratio of peak levels (C_{max}) and AUC in the present study are comparable with the ratios found with other combined OCs.[21, 22]

The pharmacokinetics of EE are best described by a two-compartment model as found by Hümpel et al.[23] and Back et al.[4] In the present study there was no evidence of an increase in serum EE between 10:00 AM and 2:00 PM after table intake as found by Back et al.,[24] after a single oral dose. Such an increase was considered indicative for enterohepatic circulation. Variable values

of the $t_{1/2}$el of EE have been found in various studies.[1] For a proper estimation of the $t_{1/2}$el, serum concentrations should be followed for at least three half-lives, because a shorter observation period will result in an underestimation of the value for $t_{1/2}$el. In the present study the last point was estimated 72 hours after dosing and the corresponding $t_{1/2}$el for EE was 29.1 hours (Table II). This value was longer than the values found in most studies but was comparable with the value estimated by Hümpel et al.[25] (26 hours). The interindividual variation in the pharmacokinetic parameters characteristic for rate (t_{max}, C_{max}) and the extent of absorbtion (AUC) is considerable (coefficient variance about 30% to 40%; Table II). This value is comparable with the variability in the parameters for EE as found in the study performed by Stanczyk et al.,[22] who used a similarly large number of volunteers (Table II). The mean serum level versus time profile for 3-ketodesogestrel after the administration of 0.150 mg of desogestrel in combination with 0.030 mg of EE is shown in Fig. 3. Mean peak levels of 3.69 ng/ml were attained within 1 to 2 hours (1.6 hours) after dosing. The calculated AUC was 35.9 ng/ml, which closely resembles the AUC found by Kuhl et al.[19] (32.0 ± 14.3). The serum level variability of 3-ketodesogestrel in the present study is of the same order of magnitude as the variability in serum levels of norethisterone,[22] levonorgestrel,[24, 25] and gestodene[10] (Table III).

It has been suggested by Goldzieher[8] that variability in plasma levels should be attributed to differences in first-pass effect. The present results indicate that the intersubject variability in the pharmacokinetics of desogestrel was comparable with that of levonorgestrel, norethisterone, and gestodene. The bioavailability of levonorgestrel[9] and gestodene[10] has been reported to be nearly 100%, whereas the bioavailability of norethisterone,[29] EE,[5] and desogestrel[27] was less. The variability in serum levels for all these compounds was, however, comparable. Therefore we conclude that the comparable variability cannot be related to possible differences in first-pass effects.

SESSION II. GASTROINTESTINAL METABOLISM OF ORAL CONTRACEPTIVE STEROIDS

Chairman: J. Hammerstein

Gastrointestinal metabolism of contraceptive steroids

David J. Back, PhD, Steven Madden, BSc, and Michael L'E. Orme, MD
Liverpool, England

A number of oral contraceptive steroids undergo first-pass metabolism in the gastrointestinal mucosa. Ethinyl estradiol (mean systemic bioavailability 40% to 50%) is extensively metabolized, principally to a sulfate conjugate. In vivo studies that use portal vein catheterization and the administration of radiolabeled ethinyl estradiol have shown that the fraction of steroid metabolized in the gut wall is 0.44. In vitro studies with jejunal biopsy samples or larger pieces of jejunum or terminal ileum mounted in Ussing chambers have indicated that more than 30% of added ethinyl estradiol is sulfated. The progestogen desogestrel is a prodrug that is converted to the active metabolite 3-ketodesogestrel. Substantial first-pass metabolism of desogestrel occurs in the gut mucosa, with evidence from Ussing chamber studies for the formation of the active metabolite. Another progestogen, norgestimate, is also metabolized by the gut wall in vitro of which the principal metabolite is the deacetylated product, norgestrel oxime. It seems very likely that this will also occur in vivo. Drug interactions occurring in the gut wall have been reported with ascorbic acid (vitamin C) and paracetamol. (Am J Obstet Gynecol 1990;163:2138-45.)

Key words: Intestinal metabolism, contraceptive steroids, ethinyl estradiol, desogestrel, norgestimate

The first suggestion that estrogens were metabolized in the gastrointestinal mucosa came from studies performed by Lehtinen et al.[1, 2]; they showed the formation of a glucuronide conjugate of 17β-estradiol in rat duodenal slices. Further studies in the rat confirmed the formation of this metabolite[3] and also demonstrated the metabolism of estriol to the 16- and 17β-monogluconides. At the same time, Diczfalusy et al.,[4, 5] demonstrated the formation of glucuronide conjugates of estriol and estrone in patients either with a biliary fistula or who required surgery on the small intestine and in whom an isolated loop of small intestine was formed. A number of other studies on the gut wall metabolism of natural estrogens were subsequently reported, and these have been reviewed by Adlercreutz et al.[6] Interest in the possible intestinal metabolism of synthetic estrogens (and progestogens) has been much more recent. The stimulus to work in this area was the finding that ethinyl estradiol (EE_2) was well absorbed in women but had only a mean systemic bioavailability of 40% to 50%.[7] The possibility of presystemic metabolism in both the gut wall and the liver had to be considered. This article summarizes studies, both in vitro and in vivo, on the gut wall metabolism of EE_2 in humans. The intestinal metabolism of the progestogens desogestrel and norgestimate is also considered.

Intestinal metabolism of EE_2

In vivo studies: Portal vein catheterization. Five patients (ages 58 to 70 years; three men and two women) who had recently undergone surgery for carcinoma of the colon and had then received 5-flurouracil administration into the portal vein by a cannula inserted through the remnant of the umbilical vein participated in the study.[8] After an overnight fast, a single tablet of

Reprinted from Rogers SM, Back DJ, Orme ML'E. Intestinal metabolism of ethinyloestradiol and paracetamol in vitro: studies using Ussing chambers. Br J Clin Pharmacol 1987;23:727-34.

Results are mean ± SD (n = 10) of tissues from five patients.

Eugynon 50 (50 μg EE_2 incorporationg 65 μCi ^{3}H-EE_2; 500 μg norgestrel) was given by mouth. Before dosing and at 10, 20, 30, 40, 50, and 60 minutes after dosing, blood samples were taken simultaneously from the portal vein cannula and from a cannula inserted into a forearm vein. Total radioactivity and ether extractable radioactivity (before and after hydrolysis with β-glucuronidase/sulfatase enzyme) were determined.

The following equations for the rate of drug absorption across the gastrointestinal mucosa (dAa/dt) and the rate of metabolism of EE_2 by the mucosa (dAm/dt) were used to calculate the fraction of EE_2 metabolized.

$$\frac{dAa}{dt} = Q_{HP} \cdot C_{HP.T} - Q_{HP} \cdot C_{A.T} \qquad (1)$$

where Q_{HP} is the blood flow in the hepatic portal vein, $C_{HP.T}$ is the concentration of total radioactivity in the hepatic portal vein, and $C_{A.T}$ is the concentration of total radioactivity in the mesenteric artery.

$$\frac{dAm}{dt} = Q_{HP} \cdot C_{HP.M} - Q_{HP} \cdot C_{A.M} \qquad (2)$$

where $C_{HP.M}$ is the concentration of metabolite in the hepatic portal vein and $C_{A.M}$ is the concentration of metabolite in the mesenteric artery.

With the assumption that $C_{A.T} = C_{V.T}$ and $C_{A.M} = C_{V.M}$, where $C_{V.T}$ and $C_{V.M}$ are the concentration of total radioactivity or metabolite in the peripheral vein, integration of equations 1 and 2 yields:

Amount of total drug absorbed

$$(D) = Q_{HP}\,(AUC_{HP.T} - AUC_{V.T})$$

and

Amount of conjugate absorbed

$$(A_M) = Q_{HP}\,(AUC_{HP.M} - AUC_{V.M})$$

Therefore the fraction of EE_2 metabolized in the gut wall on the first pass (fm_G)

$$fm_G = A_{M/D}\frac{(AUC_{HP.M} - AUC_{V.M})}{AUC_{HP.T} - AUC_{V.T})}$$

The mean fraction of EE_2 metabolized in the gut wall was 0.44 (Table I). This was nearly twice as much as that in the liver (0.25).

Clearly there are certain limitations in this portal vein study, in that the patients were elderly, had first undergone major surgery, and had also received 5-fluouracil. However, these factors might be expected to reduce rather than enhance intestinal metabolism.

Further supportive evidence for the importance of intestinal sulfation has come from a study in which plasma concentrations of EE_2 and EE_2-sulfate were de-

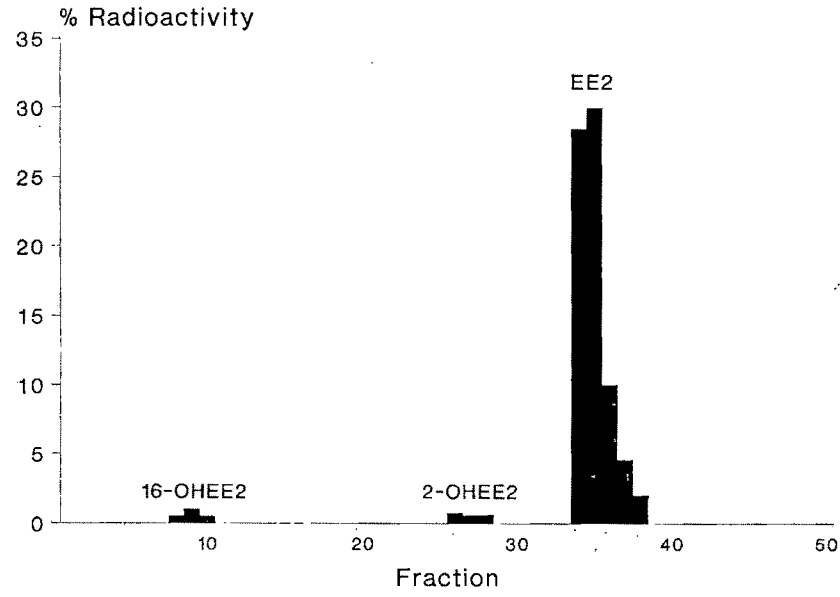

Fig. 2. A representative high-performance liquid chromatograph of an ether extract of mucosal fluid in a study with [^{3}H]-EE_2. Peak assignments are based on co-chromatography with authentic unlabeled steroids. Similar profiles were also obtained after hydrolysis with sulfatase/β-glucuronidase enzyme, indicating the presence of small amounts of oxidative metabolites in both unconjugated and conjugated fractions. (Modified from Rogers SM, Back DJ, Orme ML'E. Intestinal metabolism of ethinyloestradiol and paracetamol in vitro: studies using Ussing Chambers. Br J Clin Pharmacol 1987;23:727-34.)

termined after intravenous and oral administration of EE_2.[9] After oral dosing, the area under the curve (AUC) from 0 to 24 hours of plasma EE_2-sulfate was 18 times higher than the AUC of EE_2. After intravenous administration, the AUC of the sulfate was only six times greater than that of EE_2. These data are consistent with extensive first-pass metabolism.

In vitro studies with human jejunal biopsies. Jejunal biopsy samples were obtained from 20 subjects by means of the Quinton hydraulic biopsy sampler.[10] Samples were incubated with radiolabeled EE_2 in Krebs-Henseleit buffer for 1½ hours at 37° C. After ether extraction, the aqueous phases were subjected to hydrolysis by sulfatase in the absence and presence of glucaro-1,4-lactone. Conjugation was extensive (38% of added EE_2 was nonether extractable after incubation), and sulfation appeared to be more important than glucuronidation. Conjugates were of parent EE_2, with the extent of conjugation directly related to the weight of biopsy tissue.

It was of interest that in a parallel study with mestranol (the 3-methyl prodrug of EE_2) and levonorgestrel, only approximately 5% of both drugs was conjugated.

In vitro studies with Ussing chambers. Histologically normal jejunum or terminal ileum was obtained from five patients undergoing resections for localized tumors, diverticulosis, and Crohn disease.[11] While mounted on a glass tube, the muscularis externa was stripped off the mucosa, and then after a longitudinal incision, the mucosal sheets were mounted between two perspex chambers (Ussing chambers; Fig. 1). After the addition of radiolabeled EE_2 (2 μCi; 80 ng) to the mucosal chamber (total volume 2.5 ml of Krebs-Henseleit buffer at 37° C), sampling was undertaken from both the mucosal and serosal chambers at intervals to 2 hours. Aliquots of mucosal and serosal fluid were extracted with ether for the determination of unconjugated steroid. Aliquots of the remaining aqueous phase were incubated for 2 hours at 37° C with β-glucuronidase/sulfatase enzyme either in the presence or absence of glucaro-1,4-lactone. After extraction of liberated steroid, extracts were evaporated to dryness, and the residue was dissolved in a small volume of methanol for high-performance liquid chromatographic analysis.[12]

The overall net transport of steroid from the mucosal chamber to the serosal chamber in 2 hours was low (2.3% ± 0.8%), with the presence in the serosal chamber at that time of unconjugated (free) steroid (0.4% ± 0.3%), sulfate conjugates (0.7% ± 0.5%), and glucuronide conjugates (0.9 ± 0.8%) (Table II). In the mucosal chamber 56.6% ± 11.4% of the added drug was present as unconjugated steroid, 33.3% ± 12.4% as sulfate conjugates, and 2.1% ± 2.3% as glucuronides.

High-performance liquid chromatographic analysis of the mucosal fluid revealed some evidence of trace amounts of phase I hydroxylated metabolites (Fig. 2).

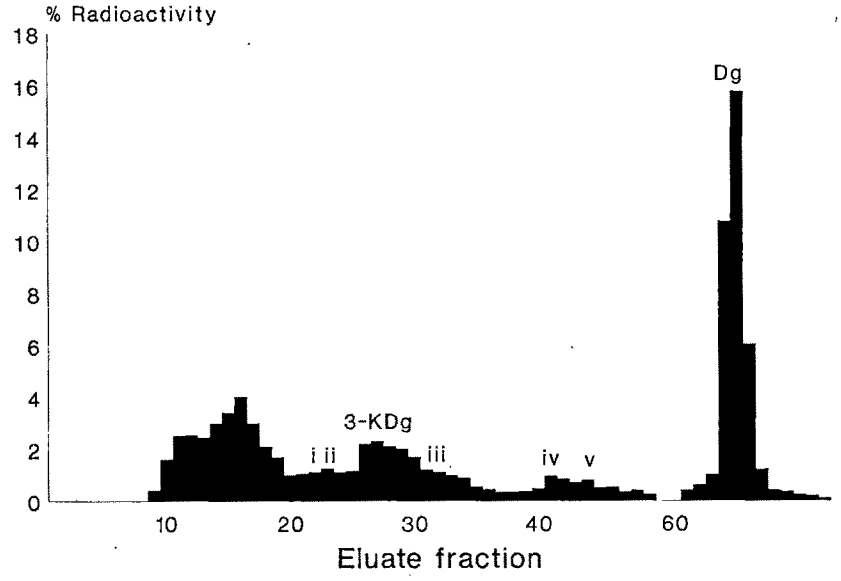

Fig. 3. Representative high-performance liquid chromatograph of an ether extract of mucosal fluid in a study with [^{3}H]-desogestrel. Solvent system was acetonitrile/water (55/45), which increased after 15 minutes to 100% acetonitrile over a 5-minute linear gradient, followed by a 30-minute isocratic elution. Peak assignment is based on co-chromatography with authentic unlabeled standards. *i*, 3β-Hydroxy desogestrel; *ii*, 3β-hydroxy, 5α-dihydro desogestrel; *iii*, 3α-hydroxy desogestrel; *iv*, 3α-hydroxy, 5α-dihydro desogestrel; *v*, 3-keto, 5α-dihydro desogestrel. From Madden S, Back DJ, Martin CA, Orme ML'E. Metabolism of the contraceptive steroid desogestrel by the intestinal mucosa. Br J Clin Pharmacol 1989;27:295-9.

These observations, which indicated in excess of 30% of EE_2 was sulfated, are in agreement with the study[10] that used small pieces of mucosa obtained at biopsy and with the findings of in vivo studies.

Thus it appears that there is a difference between the intestinal metabolism of endogenous estrogens, which predominantly form glucuronide conjugates,[4, 5] and synthetic EE_2, which is mainly sulfated.

Intestinal metabolism of desogestrel

Desogestrel (13-ethyl-11-methylene-18,19-dinor-17α-pregn-4-en-20yn-17ol) is effectively a prodrug and is metabolized to the active metabolite 3-ketodesogestrel.[13] In a pharmacokinetic study of nine subjects, Back et al.[14] demonstrated that the mean (±SD) bioavailability of 3-ketodesogestrel was 76% ± 22% (range 40% to 113%) after the oral administration of desogestrel to volunteers who also received intravenous 3-keto desogestrel. The possibility that intestinal metabolism was involved in the first-pass metabolism of desogestrel has been examined in studies with Ussing chambers.[15]

Histologically normal ileum or colon was obtained from eight patients undergoing resections for localized

Table IV. Effect of EE_2 (0.1, 1.0, and 10 μg) present in the mucosal chamber on the metabolism of desogestrel by human colon; desogestrel and metabolites were determined 2 hours after addition of [^{3}H]desogestrel (0.2 μCi; 100 ng) to the mucosal chamber

From Rogers SM, Back DJ, Orme ML'E. Intestinal metabolism of ethinyloestradiol and paracetamol in vitro: studies using Ussing chambers. Br J Clin Pharmacol 1987;23:727-34.

Results are mean ± SD of tissues (n = 10) from five patients for the controls, of tissues (n = 7) from three patients for paracetamol (50 μg), and of tissues (n = 10) from three patients for paracetamol (1 mg).

Since in the presence of paracetamol <1% of steroid was transported to the serosal side, data are presented for drug present in mucosal samples.

Significantly different from control.

*$p < 0.05$.

†$p < 0.001$.

tumors. Mucosal sheets were prepared and mounted as previously described. Radiolabeled desogestrel ([^{3}H]-desogestrel; 0.2 μCi; 100 ng) was added to the mucosal chamber. Two hours after the addition of [^{3}H]-desogestrel more than 90% of the steroid was present in the mucosal chamber. In studies with the colon, metabolite analysis (by differential enzyme hydrolysis followed by high-performance liquid chromatography) showed that 55.4% ± 11.7% (mean ± SD; N = 6) of the drug present was desogestrel, 28.9% ± 11.4% as unconjugated phase I metabolites, 13.3% ± 2.6% as sulfate conjugates, and 2.5% ± 1.5% as glucuronide conjugates (Table III).

By co-chromatography with authentic metabolites and mass spectrometry, it was shown that the active metabolite (3-ketodesogestrel) was formed in the mucosa (Fig. 3). A large peak of the radioactivity did not co-chromatograph with any known metabolites and was tentatively identified as ring hydroxylated products of 3-ketodesogestrel.

In comparison with the previously described studies with EE_2 several interesting points emerge. First, unlike EE_2, which formed only trace amounts of hydroxylated metabolites, desogestrel apparently undergoes fairly extensive oxidative metabolism. It has been previously reported that in humans the liver:intestine ratio of cytochrome P-450 is approximately 20[16] and that cytochrome P-450–dependent phase I biotransformations in the intestine is unlikely to contribute substantially to the overall metabolism of drugs in humans. Although it is difficult to draw conclusions regarding the contribution of the gut to first-pass metabolism of desogestrel in vivo, the metabolic profiles obtained in vitro give clear evidence of the potential of the gut to metabolize the steroid. Second, the formation of sulfate conjugates in preference to glucuronide conjugates

was evident with both EE_2 and desogestrel. We followed this point up in a study in which we examined the effect of adding increasing concentrations of EE_2 (100 ng, 1 and 10 μg) to Ussing chambers containing radiolabeled desogestrel (i.e., a situation analogous with in vivo, in which the two steroids are present in the combined oral contraceptive (OC). Desogestrel sulfation was reduced by 32%, 49%, and 48% in the presence of 0.1, 1, and 10 μg of EE_2, respectively (Table IV). The D rings of desogestrel and EE_2 are identical, and therefore it is possible that substrate competition exists for the same sulfotransferase enzyme, although some depletion of the PAPS (3′-phosphoadenosine-5′-phosphosulfate) pool by increasing EE_2 concentrations cannot be ruled out.

Intestinal metabolism of norgestimate

The possibility has been raised, principally on the basis of studies in female rhesus monkeys,[17] that metabolites of norgestimate (d-13-ethyl-17-acetoxy-18,19-dinor-17α-pregn-4-en-20-yn-3-oxime) and not norgestimate may be responsible for receptor binding. Sisenwine et al.[17] concluded that norgestimate appears to be a prodrug that is rapidly deacetylated to d-norgestrel-3-oxime, which is then hydrolyzed to d-norgestrel. The involvement of the intestinal mucosa in norgestimate metabolism was examined in studies with Ussing chambers.

Histologically normal terminal ileum was obtained from patients undergoing various resections, and the mucosal sheets were mounted in Ussing chambers. Radiolabeled norgestimate (0.2 μCi; 10 ng) was added to the mucosal chamber with subsequent sampling at 15, 30, 60, and 120 minutes. Conjugates were determined by hydrolysis with β-glucuronidase–sulfatase enzyme and metabolites by radiometric high-performance liquid chromatography with a mobile phase of methanol/water (70/30 v/v). Metabolite identification was by co-chromatography with authentic standards. A time course of metabolite production by intestinal mucosa is shown in Fig. 4. Note that after 2 hours of incubation, 46.3% ± 18.4% (mean ± SD) of the radioactive drug present was as unchanged norgestimate, 41.5% ± 21.6% as norgestrel oxime (deacetylated norgestimate), 4.5% ± 1.6% as norgestrel, 2.3% ± 2.3% as norgestrel acetate (loss of oxime group), and 3.6% ± 2.5% as conjugates.

These studies show very clear evidence of norgestimate metabolism, of which the principal metabolite is the deacetylated product norgestrel oxime. It seems highly probable that this will occur in vivo.

Interactions of possible clinical significance in the gut wall

Ascorbic acid. Ascorbic acid (vitamin C) forms a sulfate in the gut wall and influences the metabolism and bioavailability of other drugs that are conjugated with sulfate (e.g., salicylamide).[18] Therefore we studied the effect of concurrent administration of ascorbic acid in five women receiving long-term OC therapy.[19] The volunteers were studied in two consecutive menstrual cycles during the last week of OC administation. In random order, one of these acted as a control, and in the other week the OC was given with a 1 gm dose of ascorbic acid. Blood samples were obtained 6 and 24 hours after the OC was taken on three consecutive days and plasma was analyzed for EE_2 and levonorgestrel by radioimmunoassay.

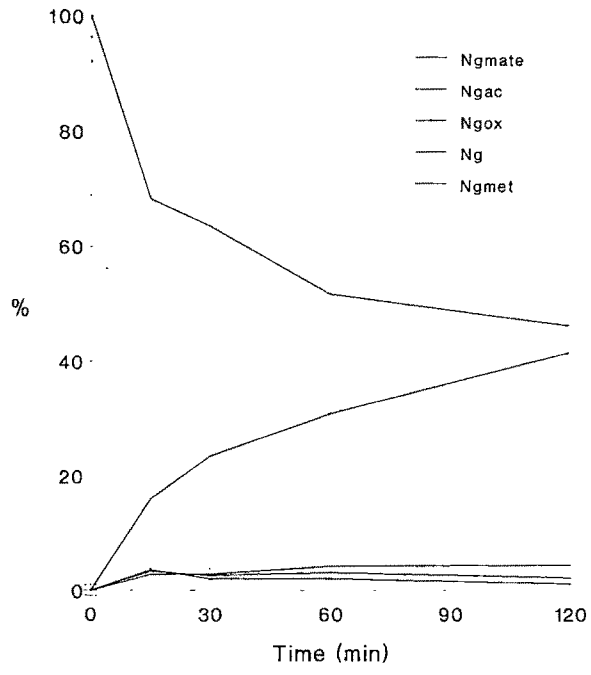

Fig. 4. Time course of metabolism of norgestimate by human mucosa (terminal ileum).

In the presence of ascorbic acid, the mean EE_2 concentrations increased at 6 hours from 49 to 57 pg · ml^{-1} (+16.3%) and at 24 hours from 21 to 31 pg · ml^{-1} (+47.6%). It was concluded that this increase was related to a decrease in gut wall metabolism caused by competition for sulfation and that high doses of vitamin C would effectively cause a low-dose OC to become a high-dose preparation.

Paracetamol. Histologically normal jejunum or terminal ileum was obtained from six patients undergoing resections, and mucosal sheets were mounted in Ussing chambers as previously described. Paracetamol, 50 μg or 1 mg, was added to the mucosal chamber (concentrations equivalent to 20 μg · ml^{-1} and 400 μg · ml^{-1} in the bathing fluid). After a period of 20 minutes, radiolabeled EE_2 (80 ng; 2 μCi) was added to the chamber, and samples were removed at intervals to 2 hours. EE_2 and conjugates were determined after differential hydrolysis and extraction.[11]

Table VI. Effect of a single dose of paracetamol (1 gm) on the AUC obtained for EE_2 for the time periods 0 to 3, 0 to 6, 0 to 11, and 0 to 24 hours

Results are mean ± SD of six subjects except †where data are from three subjects.

*Significantly different from controls, $p < 0.05$.

The effect of paracetamol on EE_2 metabolism is shown in Table V (mucosal data only). In the presence of 50 μg of paracetamol, there was a significant decrease in total conjugates, which resulted from a decrease in formation of EE_2-sulfates. With the increase in paracetamol to 1 mg, unconjugated steroid was increased from a mean value of 56.6% (control) to 88.1%, total conjugates decreased from 35.3% to 10%, and EE_2-sulfates decreased from 33.3% to 6.8%.

These observations indicated that competition for sulfation occurred when both drugs were presented to the intestinal mucosa. Rogers et al.[11] suggested that a decrease in the PAPS (3′-phosphoadenosine-5′-phosphosulfate) pool was responsible for the decrease in steroid conjugation.

This in vitro study was followed up by examining the effect of a conventional single dose of paracetamol (1 gm) on the plasma concentrations of EE_2 in the 24-hour period after ingestion of an OC (Table VI). The study was performed in six healthy volunteers in two consecutive cycles. Plasma EE_2, EE_2-sulfate (after hydrolysis), and levonorgestrel were measured by radioimmunoassay.

The area under the plasma concentration/time curve (AUC_{0-24}) of EE_2 was significantly increased by 22% after paracetamol administration (control 2221 ± 291; after paracetamol, 2702 ± 452 pg · ml^{-1} × hour; mean ± SD; $p < 0.05$; Table VII). Plasma concentrations of LNG were unaltered by concurrent paracetamol administration.

It was concluded that the increase in plasma EE_2 concentrations resulted from a reduction in sulfation of the steroid, mainly in the gut wall, and that this interaction could be of clinical significance in women on OCs who take paracetamol regularly.

In conclusion, the studies described herein have highlighted the importance of gut wall metabolism in the overall disposition of some contraceptive steroids. EE_2 is primarily sulfated, desogestrel undergoes oxidative metabolism, whereas norgestimate principally undergoes hydrolysis with removal of the acetate group.

One of the main concerns in OC administration is to ensure that plasma concentrations are (1) adequate to achieve the contraceptive effect and (2) no higher than necessary so as to predispose to toxicity. The interactions occurring in the gut wall that have been reported (i.e., ascorbic acid and paracetamol) fall into the second category in that plasma EE_2 concentrations are raised as a result of competition for sulfation. It is also important to know if in disease states of the gastrointestinal tract (e.g., celiac disease and Crohn disease), there is any modification of metabolism. We have recently found that EE_2 sulfation was reduced by more than 60% in patients with celiac disease compared with control subjects. After a period of gluten-free treatment, metabolic activity was restored.[21] Also in vivo the bioavailability of EE_2 is significantly greater in untreated patients with celiac disease compared with healthy control subjects.

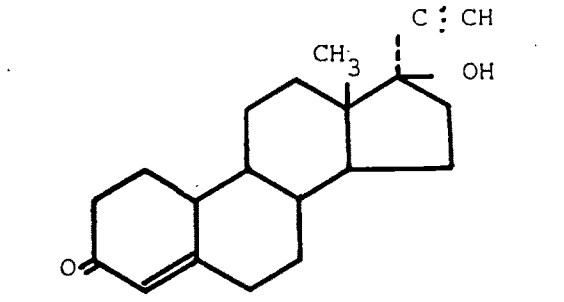
Factors affecting the enterohepatic circulation of oral contraceptive steroids

Michael L'E. Orme, MD, and David J. Back, PhD
Liverpool, England

Oral contraceptive steroids may undergo enterohepatic circulation, but it is relevant for only estrogens, because these compounds can be directly conjugated in the liver. Animal studies show convincing evidence of the importance of the enterohepatic circulation, but studies in humans are much less convincing. The importance of the route and the rate of metabolism of ethinyl estradiol are reviewed. Some antibiotics have been reported anecdotally to reduce the efficacy of oral contraceptive steroids, but controlled studies have not confirmed this observation. Although gut flora are altered by oral antibotics, the blood levels of ethinyl estradiol are not reduced, and one antibiotic at least (cotrimoxazole) enhances the activity of ethinyl estradiol. (Am J Obstet Gynecol 1990;163:2146-52.)

Key words: Enterohepatic circulation, contraceptive steroids, ethinyl estradiol, antibiotics, drug metabolism

Oral contraceptive steroids have now been in widespread use throughout the world for at least 25 years. It is currently estimated that they are used on a regular basis by 55 to 60 million women. However, scientific knowledge about steroids is still deficient in many areas, particularly about how they are handled by the body. Since the development of specific and sensitive radioimmunoassays,[1-3] we are now aware of the kinetic properties of most of the contraceptive steroids.[4] The commonly used estrogen, ethinyl estradiol (EE_2), is well absorbed from the gastrointestinal tract, but undergoes extensive, although variable, presystemic (or first-pass) elimination.[2, 3, 5] The other commonly used estrogen, mestranol, is essentially a prodrug and is metabolized by O-demethylation to EE_2 after oral absorption.[6] It appears that mestranol itself has no estrogenic activity.



The major progestogens are all well absorbed from the gastrointestinal tract. The chemical structures of norethisterone, a "first-generation" progestogen, and EE_2, are shown in Fig. 1. There are some variations between the progestogens, but in general, first-pass metabolism is less important for the older progestogens, although norethisterone has a first-pass effect of 30% to 40%.[7] Desogestrel is metabolized extensively during the absorption process (probably mainly in the liver) to 3-ketodesogestrel, which is the active progestogen.[8] The main initial metabolic step for the progestogens is A ring reduction, which may occur at either the 3 or 5 position, and two stereoisomers of each are possible, which are designated α or β. Thus 3α, 5α; 3α, 5β; 3β, 5α; and 3β, 5β tetrahydro derivatives of norethisterone and levonorgestrel have been identified.[9, 10] In humans the evidence suggests very little direct conjugation of the hydroxyl group at the 17 position for both norethisterone[11] and levonorgestrel.[12] Thus any conjugates of norethisterone or other progestogens are most unlikely to be conjugates of the active parent drug; instead, they will be conjugates of the inactive reduced metabolites of the progestogen. Thus biliary excretion of progestogen conjugates will only be of the inactive metabolites.

Enterohepatic recirculation of EE_2

The enterohepatic circulation of any drug involves initial conjugation, usually with glucuronic acid, in the liver to form a compound with a molecular weight in excess of 400. This is then eliminated in the bile and then goes to the gastrointestinal tract. The second part of the enterohepatic circulation involves some process that regenerates the parent (active) drug, and this is then reabsorbed into the body. Conjugates are usually regarded as being too hydrophilic to be absorbed intact. Although other mechanisms are possible, the usual process involved is a hydrolytic step performed by the gut bacteria, which in most humans are present primarily in the colon.

The enterohepatic recirculation of EE_2 is illustrated in Fig. 2. EE_2 can be conjugated with both a sulfate or a glucuronide moiety. Sulfation occurs primarily in the small intestinal mucosa,[13, 14] whereas conjugation with

NORETHISTERONE

ETHINYLOESTRADIOL

Fig. 1. The chemical structures of norethisterone and EE_2.

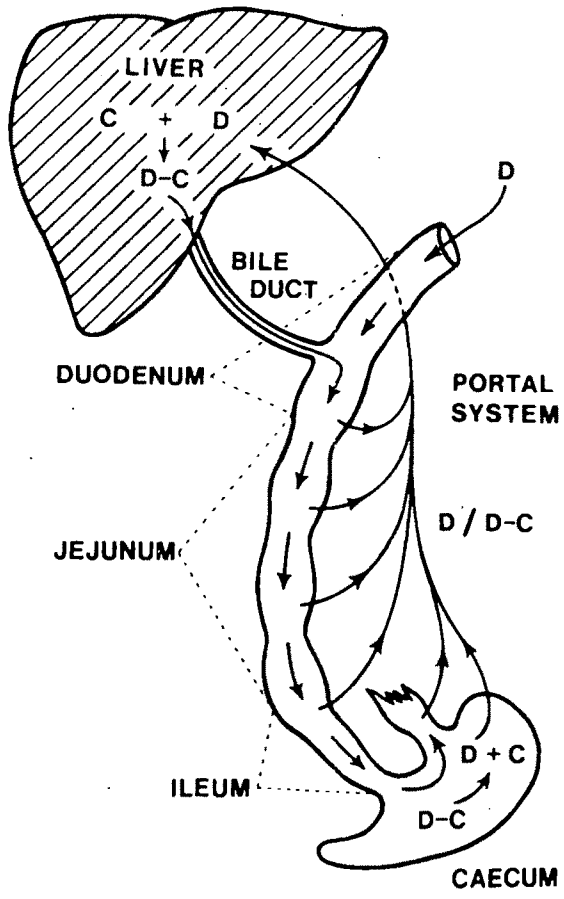

Fig. 2. Schematic representation of the enterohepatic circulation of an orally administered drug *(D)*, which is conjugated with glucuronic acid or sulfate *(C)*, to form the drug conjugate *(D-C)*, which in this example is the conjugate of EE_2.

glucuronic acid is mainly a hepatic affair.[15, 16] Conjugation of EE_2 used to be thought of as occurring primarily at the 3 position, but it is clear that glucuronidation at least can occur at the 17 position.[17, 18] These conjugates are excreted in the bile[19] and thus reach the colon. It is possible for the conjugates to reach the gut in other ways. Recent studies by Back et al.[20] with isolated human gut mucosa pieces (from which the muscularis externa is removed) mounted in Ussing chambers[21] have shown that small amounts of EE_2 conjugates can diffuse back out of the mucosa into the lumen of the gut.[20] However, this is a slow process and its relevance in vivo is not clear. It is unlikely to contribute substantially to the conjugates that are found in the gut. Once the conjugates of EE_2 reach the colon, they may be hydrolyzed by the bacteria present there to liberate unchanged EE_2, which can then be absorted into the body. This EE_2 then passes up the portal venous system to the liver for the whole process to begin again.

It is very difficult in humans to find out how important the enterohepatic recirculation of EE_2 is in practical terms. In animals there is little doubt that such a recirculation contributes substantially to blood levels of EE_2,[22] as can be shown by cutting the bile duct of one rat, catheterizing that duct, and infusing the bile into a second rat. It is, however, clearly not possible to perform this type of study in humans and even close approximations (e.g., T tube drainage) only collects a fraction of the bile produced. Fig. 3 shows a mean plasma concentration versus time profile for EE_2 compared with norethisterone in a group of five subjects. The curve for norethisterone is relatively uncomplicated and easily explicable on a two-compartment open kinetic model. The curve for EE_2 is marked by an increase in the plasma concentration at 12 to 14 hours after administration, and this is usually attributed to the enterohepatic recirculation. However, the standard error bars show that there is considerably greater interindividual variation in the kinetics of EE_2 compared with norethisterone.

Factors affecting the enterohepatic circulation of EE_2

Interindividual variation in metabolism

Rate. Examination of Fig. 3 shows that there is clearly a marked interindividual variation in the rate of metabolism of EE_2, and some of this may affect glucuron-

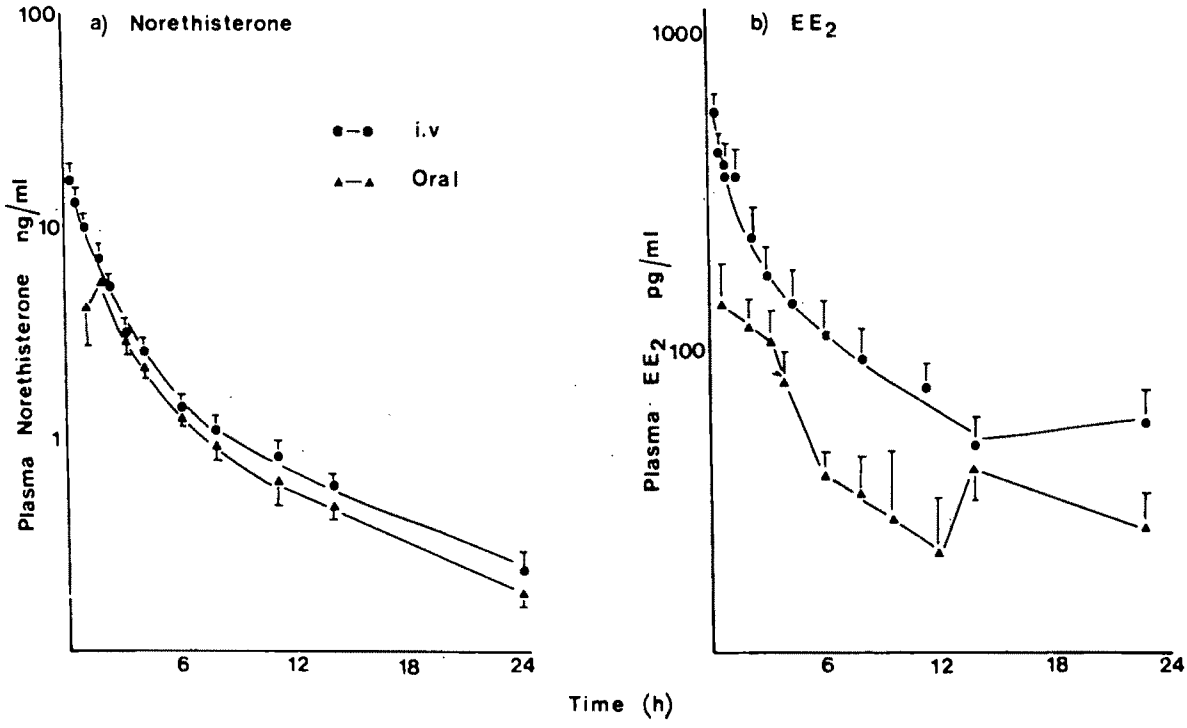

Fig. 3. Plasma concentrations of norethisterone *(a)* and EE_2 *(b)* in women after intravenous or oral administration of preparations containing norethisterone (1 mg) and EE_2 (50 μg). Each curve is the mean ± SEM of five women. (From Back DJ, Breckenridge AM, Crawford FE, et al. Drug-drug interactions: studies with oral contraceptive steroids. In: Bowers JZ, Velo GP, eds. Drug assessment criteria and methods. Amsterdam: Elsevier Science Publishers, 1979:185-206, by permission of Elsevier Science Publishers.)

idation and sulfation. In vitro studies with human gut mucosa show a variation in the sulfation of EE_2 between persons,[14] and it is likely that this also applies to glucuronidation. Drugs that are enzyme inducers are known to enhance the glucuronidation pathway as has been shown for the glucuronidation of bilirubin[23] and oxazepam.[24] Thus the known effects of enzyme inducers such as rifampicin[25] or phenobarbitone[26] in EE_2 metabolism are likely to involve both glucuronidation and hydroxylation. It is not known if enzyme inhibitors affect the glucuronidation of EE_2 in humans; however, drugs such as primaquine, which inhibit the oxidation of antipyrine in humans,[27] have no effect on the metabolism of EE_2.[28]

Route. The routes of metabolism of EE_2 are shown in Fig. 4. In most humans the main route of metabolism is by hydroxylation at the 2 position, but hydroxylation at the 4, 6, and 16 positions also occurs.[29, 30] Bolt et al.[29] showed that on average 29% of ingested EE_2 is hydroxylated at the 2 position, but in some persons this may be as high as 64%. Thus direct conjugation of EE_2 with glucuronic acid or sulfate is probably a relatively minor pathway of metabolism in most women. However, this situation may change if a person is unable to 2-hydroxylate EE_2. Maggs et al.,[31] in a study of eight patients whose bile was collected by an endoscope after a dose of ^3H-EE_2, found one woman who was unable to hydroxylate EE_2 and thus whose excretion of direct conjugates of EE_2 was increased. Genetic polymorphisms in drug metabolism are well established, and it is known that a proportion of persons are poor hydroxylators of drugs such as debrisoquine.[32] About 10% of whites belong to the poor metabolizer phenotype[33] which is inherited as an autosomal-recessive trait. The one patient in the study of Maggs et al.[31] who was unable to 2-hydroxylate EE_2 was tested for the ability to metabolize sparteine, which is metabolized by the same cytochrome P-450 as debrisoquine ($P\text{-}450_{DB}$)[34, 35] However, she was able to metabolize sparteine extensively and thus her inability to hydroxylate EE_2 was not because of a deficiency of $P450_{DB}$. Further studies are required to find out how common in the population is the inability to hydroxylate EE_2 at the 2 position. It is clear, however, that persons who are unable to perform this hydroxylation step are more likely to excrete EE_2 glucuronides and sulfate in the bile and thus have a more extensive enterohepatic circulation of EE_2.

Gastrointestinal and liver disease. Several disease processes may potentially affect the enterohepatic recirculation of EE_2, but they are unlikely to be a problem in clinical practice. Thus patients with liver disease, in whom the conjugation step may be impaired, are un-

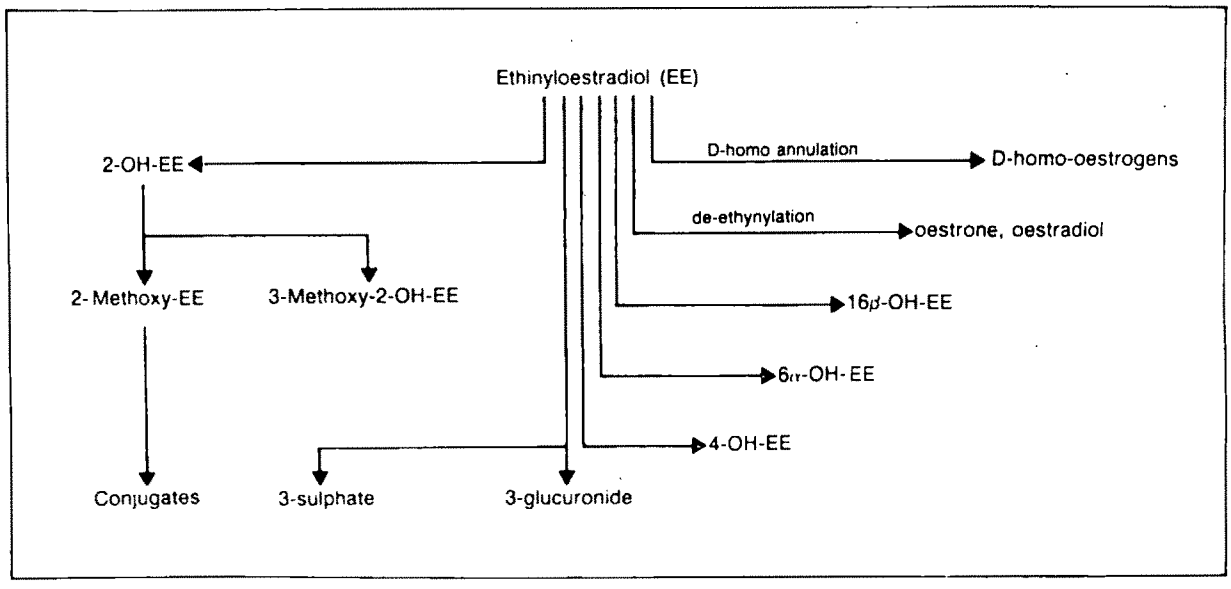

Fig. 4. Pathways of metabolism of EE_2. Metabolites may exist free or conjugated with sulfate or glucuronide. (From Clinical pharmacokinetics of oral contraceptive steroids. Clin Pharmacokinet 1988;8:95-136, by permission of Adis Press.)

likely to be given contraceptive steroids in the first place. Similarly, patients who have had bile duct surgery and in whom the flow of bile may be impaired will be most unlikely to be given oral contraceptive steroids.

However, in some gastrointestinal diseases patients who suffer from them are commonly given oral contraceptive steroids. The subject of gastrointestinal disease and its effect on the kinetics of contraceptive steroids are covered in another article in this supplement, and we will consider here only the disease processes that are likely to affect the enterohepatic recirculation.

In patients with active celiac disease, the ability of the gastrointestinal mucosa to conjugate EE_2 with sulfate is impaired.[36] Thus the bioavailability of EE_2 is actually increased in a disease that in general causes a malabsorptive state. However, there is no good evidence that the enterohepatic recirculation of EE_2 is reduced, and in any case after 6 months of treatment with a gluten-free diet, normal sulfate conjugation is restored to the gut mucosa.

The breakdown of the EE_2 conjugate is normally performed by gastrointestinal microorganisms, and disease processes that disturb them may alter the enterohepatic circulation of EE_2. In cystic fibrosis, in which microorganisms may be found throughout the small intestine, the kinetics of EE_2 are not different from normal, with no obvious major alteration in the enterohepatic recirculation.[37] In patients who have had an ileostomy (e.g., for ulcerative colitis), the colon is usually removed and thus the normal colonic microflora will be absent, because the ileum is usually relatively free of microorganisms. In patients who have had an ileostomy, the absorption of EE_2 is unimpaired, but there is no secondary peak of EE_2 levels at 12 to 14 hours, indicating, as expected, no (or very little) enterohepatic circulation of EE_2.[38] However, a rough comparison between the area under the plasma concentration versus time curve (AUC) for EE_2 over a 24-hour period in these patients compared with the AUC in normal volunteers given an identical dose of EE_2 reveals no significant difference between the values. Although not a controlled observation, this suggests that the contribution of the enterohepatic circulation to the overall kinetics of EE_2 is a small one in most patients. It would be interesting to compare the kinetics of EE_2 in patients before and after total colectomy, but such studies would be difficult to perform.

Changes in gut flora. As previously mentioned, gastrointestinal microorganisms are normally confined to the colon and rectum except in disease processes in which the rest of the gut may then contain bacteria. It is clear that the colon contains a very large number of bacteria and that the nature of these bacteria may vary from time to time.[39] Their nature probably depends on a variety of factors, but particularly by the food we eat and the water that we drink. Thus our gastrointestinal microorganisms may change subtly as the diet changes. More dramatic changes in gut flora, which are often accompanied by diarrhea, may be associated with travel to new destinations, where different foods and water sources may produce more profound changes in the gut flora. The hydrolysis of EE_2 conjugates is not performed by all bacteria in the gut but seems to be particulary performed by the *Clostridia* species. The work

Table I. Hydrolysis of estrone sulfates by isolated human fecal microorganisms[40]

Microorganism	*% hydrolysis*
Bacteroides	2.9
Staphylococci	6.1
Lactose-fermenting *Coliforms*	5.0
Nonlactose-fermenting *Coliforms*	3.8
Clostridia A	72.5
Clostridia B	0
Hemolytic streptococci	0.7

Further identification of *Clostrida* subtypes was not possible.

Table II. Percentage hydrolysis of estrone sulfate by human fecal microorganisms before and after preteatment with ampicillin (500 mg, four times daily, for 1½ days)[40]

Sample	*Control*	*After ampicillin*
1	95.0	1.8
2	92.6	5.4
3	90.3	8.2
4	90.1	7.5
Mean ± SEM	92.0 ± 1.0	5.7 ± 1.2*

*$p < 0.001$.

of Chapman[40] (Table I) illustrates the amount of hydrolysis of EE_2 conjugates performed by various gastrointestinal microorganisms.

Effect of antibiotics on gut flora. Antibiotics may interfere with the enterohepatic recirculation of EE_2 by killing off the *Clostridia* that are responsible for the hydrolytic process. Thus any conjugates of EE_2 would now be lost in the feces, because they are too hydrophilic to be absorbed, and potentially the plasma concentration of EE_2 would fall. Sporadic reports appeared in the literature of women who have become pregnant while taking antibiotics alone with their oral contraceptive steroids.[41-43] The number of these reports is fairly small, and some authorities have stated that the interaction is of no clinical importance.[44] However, most data sheets for the oral contraceptive steroids warn that alternative contraceptive precautions should be taken when antibiotics are taken at the same time as oral contraceptive steroids. The Committee of Safety of Medicines in the United Kingdom received 63 reports of failure of contraception in women receiving antibiotics along with their oral contraceptive steroids from 1973 to 1984.[45] The antibiotics implicated included ampicillin, penicillin, tetracyclines, and cotrimoxazole. Since the yellow card system of reporting adverse effects to the Committee on Safety of Medicines represents a considerable degree of underreporting, it is possible that this interaction may be of clinical importance, but which view is correct?

In animal studies the enterohepatic recirculation of EE_2 is extensive and is clearly diminished by treatment with antibiotics such as ampicillin or neomycin.[22] The degree of reduction of the enterohepatic recirculation can be correlated with the degree of suppression of the gut microflora. However, as already stated, it is difficult to duplicate these studies in humans. Controlled clinical studies have generally failed to show any systematic interaction between antibiotics and oral contraceptive steroids. Thus ampicillin[46-48] had no effect on the kinetics of EE_2 in women, even though the ability of the human fecal microorganisms to hydrolyze steroid conjugates is dramatically reduced by treatment (Table II).[40] Similarly, tetracycline had no clinical effect in practice.[49] In a study with cotrimoxazole there was actually a significant increase in the plasma level of EE_2 accompanied by a further suppression of follicle-stimulating hormone levels.[50] This was attributed to an inhibition of the hydroxylation of EE_2 by the sulfonamide component of cotrimoxazole. There was no evidence that the enterohepatic circulation of EE_2 had been impaired. Although these studies show no systematic interaction between antibiotics and oral contraceptive steroids scientific studies have involved no more than 50 persons, and it is possible that certain persons may be at risk. We suggest that the interaction may involve those women who are unable to hydroxylate EE_2 at the 2 position (and thus excrete larger amounts of EE_2 conjugates) and whose gut bacteria are particularly susceptible to being killed by the antibiotic used. The prevalence of this interaction is hard to guess since more work is required, but it may be close to the natural failure rate of the combined oral contraceptive steroids (0.3 to 0.5 per 100 women-years of use). One objection to some of the studies of interactions between oral contraceptive steroids and antibiotics is that bacteria in the gut develop resistance to antibiotics such as ampicillin fairly rapidly. If the antibiotic interaction is looked for after 2 weeks of antibiotic therapy, it may be missed because resistance to ampicillin develops over 5 to 6 days.[51] However, several of the aforementioned studies[46, 50] looked at the interaction during a 7-day course of antibiotics starting 3 days after the start of the antibiotic therapy at a time when resistance would be unlikely to have developed, and still no interaction was detected.

In conclusion, there is limited evidence that the enterohepatic circulation of steroids exists in humans, at least for EE_2. Some of the factors that affect that enterohepatic circulation are understood, but much more information is required before we can fully evaluate the role of the enterohepatic circulation of EE_2 and the factors that affect it.

SESSION III. HEPATIC METABOLISM OF ORAL CONTRACEPTIVE STEROIDS

Chairman: M. Orme

Interactions with oral contraceptives

Kenneth Fotherby, PhD
London, England

The interaction of a range of different factors with the pharmacologic activity of oral contraceptives is reviewed. Pharmacokinetic interactions with oral contraceptives may occur (1) during absorption and extrahepatic circulation, (2) by interfering with protein binding, and (3) during hepatic metabolism. The hepatic mixed function oxidase system, which is mainly responsible for the metabolism of oral contraceptives, is affected by several different factors and is easily induced. Nutrition affects the activity of many drugs, but information regarding oral contraceptives is meager. Both pharmacokinetic and pharmacodynamic interactions, which may be synergistic or antagonistic, between the estrogen and gestagen components of oral contraceptives, are important, but there is no correlation between the rate of metabolism of the two components. Evidence suggests that some anticonvulsant, antibiotic, and antibacterial drugs may reduce the efficacy of oral contraceptives. Instances of interactions of other therapeutic agents are reported infrequently. The incidence of serious interactions is low and does not appear to have been reduced with low-dose oral contraceptives, probably because of large intersubject variability in the pharmacokinetics of oral contraceptives. (Am J Obstet Gynecol 1990;163:2153-9.)

Key words: Drug interactions, oral contraceptives, pharmacokinetics, absorption, protein binding, metabolism

Considering (1) the wide variety of drugs available, (2) the large proportion of the population consuming both prescribed and over-the-counter drugs, (3) that nutritional factors may affect drug action, and (4) that many drugs have similar metabolic pathways, it is perhaps surprising that drug interactions are not more common than they appear to be. This article is concerned only with the effects of other agents on the biologic activity of contraceptive steroids, and will not examine the changes in drug activity that may be encountered in women using oral contraceptives (OCs). As far as contraceptive steroids are concerned, a clinically important decrease in their efficacy because of interaction with other drugs appears to occur in a very small minority of women (<5%), and the possible reasons why the incidence is so low are considered later. This article examines only the possible loci in the metabolism of contraceptive steroids in which other drugs and nutrients might interact. A detailed listing of all the drugs likely to interact with the contraceptive steroids will not be provided, since many excellent accounts of this area are available.[1-4]

The interaction of drugs and nutrients with OCs may interfere with their pharmacokinetic behavior, pharmacodynamic actions, or both. In addition, with combined OCs the interaction of the estrogen and gestagen components is of great importance.

Pharmacokinetic interactions

The three main areas in which pharmacokinetic interactions may occur between contraceptive steroids and other drugs are (1) absorption, (2) serum protein binding, and (3) hepatic metabolism.

Absorption. There are two mechanisms by which drugs may interact with the absorption of contraceptive steroids: by affecting the absorptive process itself or by affecting the intestinal flora.

Absorption of steroids may be impaired when the rate of which they pass through the gastrointestinal tract is markedly increased because of increased intestinal motility; for example, in subjects either using laxatives or with severe or prolonged diarrhea. Ethinyl estradiol (EE) and some gestagens, such as norethisterone (NET), undergo extensive (40% to 60%) first-pass metabolism, much of which occurs in the intestinal wall. Absorption appears to occur mainly in the upper part of the intestine, since the bioavailability of EE and levonorgestrel (LNG) is not decreased by ileostomy or after jejunoileal bypass. Phase 1 metabolism of steroids can be demonstrated with intestinal tissue in vitro, and intestinal tissue contains cytochrome P-450, but under normal in vitro conditions, phase 1 metabolism by the intestine appears to be unimportant. However, the ex-

tent to which such metabolism is increased after the administration of enzyme-inducing drugs has not been investigated.

Specific effects on EE, which undergoes sulfation in the intestinal mucosa, may occur with certain drugs. Since the amount of available sulfate appears to be limited, administration in high doses of other drugs that are sulfated during absorption, such as vitamin C and paracetamol, leads to competition, less EE is sulfated, and its bioavailability is improved. Conversely, when the competing drug is stopped, more sulfation of EE occurs and its bioavailability is reduced.

Contraceptive steroids also undergo an enterohepatic circulation, and this is particularly important for EE. The steroids conjugated in the liver are secreted into the intestine by way of bile and are hydrolyzed by the gut flora. If these are inhibited by the administration of antibiotics, hydrolysis of the conjugates is markedly reduced, which leads to reduced reabsorption of the steroids and an increase in the fecal excretion. The effects on the gestagens are clinically less important, since they are rapidly metabolized to biologically inactive products by the liver, mainly by reduction, and to a lesser extent by hydroxylation before conjugation and secretion in the bile. Metabolism of EE in the liver involves hydroxylation at various positions, and in subjects who are poor hydroxylators, more EE is available for conjugation and the extrahepatic circulation. In these subjects interference with the extrahepatic circulation produced by the administration of antibiotics may lead to markedly lower serum EE concentrations.

Although the effect of some antibiotics on the gut flora provides one mechanism by which the bioavailability of contraceptive steroids, particularly EE, may be decreased, whether this is the major factor involved in the few clinically important interactions that occur remains to be conclusively demonstrated.

Binding to serum proteins. The contraceptive steroids are highly bound (>95%) in blood and thus are susceptible to factors that may produce only slight modifications of the binding. Thus an insignificant 2% decrease in the amount bound could lead to a significant 50% increase in the unbound fraction on which the biologic activity of the steroids depends. EE binds only to albumin, and although interaction between drugs in respect to albumin has been demonstrated, no interaction between contraceptive steroids and this protein appears to have been reported. However, the gestagens bind both to albumin and sex hormone–binding globulin (SHBG), the extent and tightness of the binding to SHBG depending on their structure, and there is a complex equilibrium between the different fractions. Serum SHBG levels can be increased by the administration of estrogens and several other drugs. The increase in SHBG may lead to an increase in the SHBG bound fraction, mainly at the expense of the albumin bound, from which dissociation occurs readily. Because contraceptive steroids are administered on a continuing basis, their serum concentrations will increase until a steady state is reached and a fresh equilibrium is formed among the different fractions; at this point the proportion unbound may be decreased, but the concentration of unbound may be unchanged. Therefore although there may be marked changes in the relative binding, these changes are unlikely to influence the efficacy of contraceptive steroids. These interactions between estrogen, gestagens, and SHBG are considered in more detail in a recent article.[5]

Hepatic metabolism. The most important locus of drug interaction appears to be the mixed function oxidase system of the liver endoplasmic reticulum. This system occurs in several other tissues, but for most drugs the liver is the major site. The enzyme system has a low specificity, performing a number of different metabolic transformations, all of which involve cytochrome P-450, cytochrome C reductase, a flavoprotein, and reduced nicotinamide adenine dinucleotide phosphate, and its activity is stimulated by many drugs. As a result, not only is the administered drug metabolized more quickly, with a decrease in its blood concentration and biologic activity, but so are several other drugs that may be administered concurrently. There are a number of distinct P-450s,[5] each of which may be under separate genetic control, and this may account for some of the interindividual variability in the rate of drug metabolism. The low specificity of the enzyme system as a whole enables it to metabolize a large number of different drugs and endogenous compounds, including the gonadal and adrenocortical steroids. Each of the distinct cytochrome P-450s may exert its main activity toward groups of substrates, with a variable amount of overlap between groups, and this accounts for the competitive inhibition that can occur among different substrates.

In addition to genetic factors, the rate of drug metabolism is influenced by a large number of environmental factors, diet, alcohol use, smoking, medication, and pathologic conditions, and all these various factors may affect the mixed function oxidase activity of the liver. Despite the low or overlapping specificity of the mixed function oxidase system, there is often marked selectively, both positional and stereochemically, in the metabolism of the substrate. With the steroids, which can be oxidized at several different sites in the molecule, the resulting hydroxylations occur to a variable extent and they can be inhibited differently by various factors. Again this suggests that multiple forms of cytochrome P-450 are present with different specifications. The relative activities of the different cytochrome P-450s ap-

pear to vary among subjects, and if so, it is important in accounting for much of the interindividual variation in drug metabolism.

The increase in the activity of the mixed function oxidase system produced by the administration of an inducing drug leads to an increase in the rate of metabolism of any contraceptive steroid the subject may use, so that the half-life of elimination of the steroid, and consequently its serum concentration and biologic effect, are decreased. Conversely, the administration of contraceptive steroids usually has an inhibitory effect on the metabolism of other drugs, which leads to an increase in their pharmacologic activity.[3]

The mechanism of this inhibitory effect in humans is not entirely clear. In animals, mainly the rat, the administration of steroids containing the ethinyl group, which encompasses most of the contraceptive steroids currently used, appears to inactivate cytochrome P-450, with a consequent decrease in the drug-metabolizing capacity of the liver. It was first demonstrated in humans in 1969 that EE may be metabolized by way of oxidation of the ethinyl group, which results in the formation of D-homosteroids and small amounts of estrone and estradiol. The oxidation of the ethinyl group is a complex reaction involving the production of numerous reactive intermediates. It appears that one or more of these metabolites interacts with, and leads to the destruction of, the heme group of cytochrome P-450, with a consequent loss of its drug-metabolizing activity both toward the steroid and other administered drugs metabolized by the mixed function oxidase system.[7-9] As a result, the pharmacologic effect of such drugs is increased. There is evidence of the in vitro formation of D-homosteroids from ethinyl steroids in the rabbit and monkey, in addition to humans.[10] Several other chemical structures, in addition to the ethinyl group, may have a similar destructive effect on cytochrome P-450.[11] An increased excretion of porphyrin precursors and coproporphyrin was reported to occur in women taking OCs,[12] which could indicate an increased turnover of cytochrome P-450 heme.

One reactive intermediate in the oxidation of the ethinyl group is an epoxide, and these compounds may also be formed by oxidation at the carbon 4-5 double bond of the steroids.[13] Interestingly, the epoxides of norethisterone (NET) and levonorgestrel (LNG) may show differences in their biologic activities.[14] However, these epoxides do not appear to be implicated in heme destruction, so that the effect produced by oxidation of the ethinyl group must be from some other reactive intermediate. Many questions still remain to be answered in respect to the inhibition of cytochrome P-450. Destruction appears to apply only to the heme part, which could readily be resynthesized; the apoprotein appears to be unaffected. So far heme destruction has been demonstrated only in the rat and in in vitro studies; whether it occurs and to what extent in humans remains to be determined. In women metabolism of the ethinyl group is only a minor pathway for EE and probably even less so for NET and LNG. Destruction of cytochrome P-450 by metabolites of the ethinyl steroids provides one mechanism by which contraceptive steroids may impair the metabolism of coadministered drugs. Whether the concentration of the reactive intermediates attains a level sufficient to impair the cytochrome P-450 system with short-term administration of contraceptive steroids seems unlikely, although drug interactions may occur under these conditions. However, with long-term use of steroidal contraception, the situation may be different. A decreased concentration of cytochrome P-450 was found in liver microsomes from monkeys that had received contraception steroids for at least 10 years,[15] although the factors responsible need to be identified. Even if heme destruction by contraceptive steroids with a consequent reduction in the drug-metabolizing capacity of the liver occurs in humans, it does not rule out the possibility that other mechanisms may exist and may be more important for the steroidal inhibition of drug metabolism. Even small doses of gestagens administered without estrogen may inhibit drug metabolism.[16] Conversely, Mills et al.[17] reported that the clearance of NET increased in women treated with 2.5 mg of NET daily. Any of these mechanisms provides a means by which contraceptive steroids are able to inhibit their metabolism, with a consequent increase over time in the pharmacologic effects.

Nutritional effects

In considering nutritional effects, it is necessary to distinguish between effects related to the quantity of the diet and those related to its quality. The former will depend on whether caloric intake in relation to energy expenditure is very low, leading to a low body mass index (BMI) and in extreme cases to anorexia nervosa, or very high, leading a high BMI and obesity. The quality will depend on the composition of a diet that is satisfactory in relation to caloric requirements. The influence of diet and nutrition on the clinical pharmacokinetics of drugs in general has been reviewed.[18]

Food intake affects absorption and bioavailability of several drugs[19, 20] but little information is available regarding contraceptive steroids.

Absorption of some lipid-soluble drugs is increased by a high-fat diet, but no investigations have been performed to determine whether this also applies to lipid-soluble contraceptive steroids. The pharmacokinetics of many drugs may be altered in obese subjects, particularly lipid-soluble drugs such as steroids, for which the apparent volume of distribution may be greatly

increased. However, in a preliminary comparison of two gestagens in healthy subjects, medroxyprogesterone acetate and NET enanthate given by intramuscular injection so that the effects of intestinal absorption were eliminated, differences in the pharmacokinetics between obese (BMI > 28) and thin (BMI < 20) subjects were minimal.[21] The elimination half-life of NET was significantly lower (mean, 5.9 hours) in a group of Indian women in a low socioeconomic group with poor nutritional status compared with that (13.4 hours) of well-nourished women in a high socioeconomic group.[22] Similar findings have also been reported for LNG.[23] The extent to which these findings can be ascribed to low serum protein levels in the former group remains to be determined. In a preliminary study of estradiol, and presumably the same situation holds for EE, 2-hydroxylation was increased and 16α-hydroxylation was decreased in anorexic subjects, whereas the reverse was observed in obese subjects.[24]

High-protein diets appear to stimulate the activity of the hepatic drug–oxidizing system, with a consequent increased rate of metabolism of many drugs. The 2-hydrozylation of estradiol is enhanced but apparently without any concomitant change in 16α-hydrozylation,[18] and the activity of the hepatic 5α-reductase is decreased. High-carbohydrate diets decrease 2-hydrozylation. A low-fat diet was also reported to increase 2-hydroxylation of estradiol and to decrease 16α-hydroxylation,[25] although this diet was also probably a high-protein one. Diet also has a marked influence on endogenously secreted androgens in humans,[26] and by analogy might be expected to affect the metabolism of gestagens. Certain specific nutrients, such as charcoal-broiled beef and cruciferous vegetables, stimulate the hepatic mixed function oxidase system.

Whether metabolism of contraceptive steroids differs between vegetarians and nonvegetarians is still controversial. Vegetarian diets tend to contain less fat and more fiber than nonvegetarian diets, and these differences appear to influence the metabolism of endogenous estrogens, which leads to a decrease in plasma estradiol concentrations.[27] This decrease might be partly caused by a decrease in the enterohepatic circulation. However, there were no significant differences in the pharmacokinetics of NET between lactovegetarian and nonvegetarian women.[28] One determinant of whether there are differences in drug metabolism between vegetarians and nonvegetarians appears to be the amount of protein in the diet.

In many of the situations discussed above, changes occur in serum SHBG concentrations, and while these changes will not affect EE, which does not bind to SHBG, they will affect the unbound biologically active fraction of the gestagens. Serum SHBG shows an inverse relationship to body weight, being low in obese subjects and increased in anorexic subjects. SHBG may also be increased in subjects consuming a low-fat diet and in vegetarians. In the latter this may be partly from absorption of phytoestrogens in the fiber-rich diet. The level of free fatty acids in serum affects the binding of endogenous sex hormones to serum proteins and increases their biologically active unbound fractions.[29, 30] Therefore it seems likely that contraceptive steroids, which elevate serum lipid levels, will be similarly affected.

Estrogen-gestagen interactions

Interaction between the estrogen and gestagen components of combined OCs may occur both at the pharmacodynamic and pharmacokinetic levels. In respect to pharmacodynamics, the interaction may be synergistic or antagonistic, whereas in some pharacodynamic responses the two components may act independently, for example, the effect of estrogen in elevating the levels of cortisol-binding globulin or triglyceride concentrations in serum. For four monophasic combined OCs containing approximately the same dose of EE but with different gestagens, the increase in triglyceride concentrations was approximately the same. Examples of synergism between the two components would be the transformation of a proliferative into a secretory endometrium and the inhibition of ovulation. With the low doses of EE and gestagen in currently used OCs, ovulation is inhibited in almost all treatment cycles when the two components are coadministered, whereas neither component alone in the same dose would produce consistent inhibition.

For most pharmacodynamic responses, the interaction is an antagonistic one, for example, the effects on high-density lipoprotein cholesterol, in which the increase produced by EE can be suppressed to a variable extent by gestagens depending on their structure and dose. The antagonistic action can clearly be seen in the effect on serum SHBG concentrations, for whereas the level of high-density lipoprotein cholesterol can be subject to many factors that may cause large variability in its measurement, serum levels of SHBG can be measured with precision and accuracy by simple methodology. As shown in Fig. 1, the SHBG concentration depends on the relative doses of estrogen (EE) and gestagen (NET) administered.

Evidence is accumulating for pharmacokinetic interactions between estrogen and gestagen. One point of interaction is SHBG. As indicated above, serum SHBG level is increased by estrogens, and this may affect the pharmacokinetics of those gestagens such as LNG or gestodene (GES), which bind strongly to SHBG.[5] However, whether any clinical effects result from these changes is not clear.

In a study in which women were sampled at intervals during 1 year of treatment with two OCs,[31] serum EE concentrations were consistently higher in women receiving the OC containing GES than in those receiving desogestrel, although the dose of EE was the same in both formulations. This finding suggests that the gestagen influenced the metabolism of EE. Since EE does not bind to SHBG, changes in the serum concentration of this protein cannot account for the observed effect, and it seems likely that in women taking the GES formulation, the metabolic clearance of EE was reduced to a greater extent than in those taking EE and desogestrel. The mechanism of this effect remains to be determined but considering the effect of ethinyl steroids in decreasing the activity of cytochrome P-450 (see above), one interpretation would be that GES has more pronounced inhibitory action on cytochrome P-450 than does desogestrel. In another study,[32] serum EE concentrations were consistently higher as expected in women who had taken an OC for 6 months than in a control group, but the clearance rate of EE was on average 35% lower in OC users than in control subjects, suggesting a decrease in the metabolizing capacity of the OC group. In this study metabolism of concomitantly administered theophylline was also decreased, suggesting the reduction in metabolic capacity was a generalized effect; again it seems reasonable to postulate that the findings are the result of an inhibitory effect of ethinyl steroids on cytochrome P-450 activity.

The increased levels of LNG in women using OCs containing EE and LNG compared with those receiving the same dose of LNG without EE has been attributed to the EE-induced increase in SHBG and the binding of LNG to SHBG, with a consequent reduction in its clearance and rate of metabolism. However, as demonstrated recently,[33] this conclusion is erroneous. Thus the slower rate of metabolism of LNG on continued dosing must be the result of other factors. Another study[34] found that the clearance rate of LNG decreased and the half-life of elimination increased in long-term users of a OC containing LNG and EE. Therefore both of these findings suggest an increase in the resistance of LNG to metabolism on continued dosing, and again this may be the result of a decrease in the activity of the cytochrome P-450 system.

In a study of the pharmacokinetics of NET and EE in a large group of women taking an OC containing these contraceptive steroids,[35] no correlation was found between the rate of metabolism of the two steroids as measured by their half-lives of elimination. Although these two closely related steroids are metabolized by the hepatic drug–metabolizing system, this lack of correlation suggests that the metabolic reactions were catalyzed by different enzymes or different variants of cytochrome P-450.

Smoking

Smoking will increase the metabolism of some drugs, whereas others are unaffected. Similarly, the rate of metabolism of some endogenous steroids, such as cortisol and progesterone are reported to be increased, whereas that of others, such as estrogens and testoterone are unchanged or decreased. The cause of the variability is unclear. Smoking leads to the production of a large number of chemicals, particularly the polycyclic aromatic hydrocarbons, which are stimulators of the hepatic drug–metabolizing system. Evidence of an effect on this system is supported by the finding[36] that 2-hydroxylation of estradiol was greater in smokers (43%) than in nonsmokers (25%). In a preliminary study[37] the rate of metabolism of EE and LNG was not affected by smoking, and variable results were obtained by Kanarkowski et al.[34] Clearly, definitive studies of the effect of smoking on the metabolism of contraceptive steroids are required.

Conclusions

It seems clear[38, 39] that the two main areas of drug interaction that affect the pharmacokinetics and efficacy of the OCs are first the effect of some, but not all, anticonvulsant drugs, antibiotics, and antibacterial agents on the hepatic drug–metabolizing system, which leads to an increased rate of metabolism of contraceptive steroids, and second, the effect of some, but again not all, antibiotics and antibacterial drugs on the absorption and enterohepatic circulation of contraceptive steroids; this latter effect will mainly reduce the serum concentration of EE, and the gestagen will be little affected. Effects of other therapeutic agents on contraceptive steroids are reported much more rarely, and in

these circumstances it is difficult to know whether the reduced efficacy of the OC is caused by the concomitantly administered drug or by some other event, such as the subject forgetting to take one or more pills, particularly near the beginning or end of the treatment period, or to the infrequent but nevertheless adequately documented occurrence of ovarian activity, leading in a few instances to breakthrough ovulation and the risk of pregnancy.[40, 41] Even when there is the possibility of an interaction, only in a small proportion of women (probably well under 5%, although no proper epidemiologic studies have been performed to determine the incidence of drug interactions with the OCs) will the interaction occur to such an extent that there is a decrease in the efficacy of the OC, thereby leading to the risk of pregnancy. It might be expected that serious interactions would be more common now that most OCs used contain low doses of contraceptive steroids. However, there appears to be little evidence to support this contention.[39] One reason for this may be the marked interindividual variability in the pharmacokinetics of contraceptive steroids.[42] One might postulate that serious interactions would occur only in those women who are fast metabolizers and therefore have low serum concentrations of contraceptive steroids and in those women whose liver enzyme systems are particularly susceptible to induction.

More information is required regarding the mechanisms by which contraceptive steroids produce their inhibitory effect on many coadministered drugs, and particularly since it is important with regard to long-term use of OCs, the way in which contraceptive steroids may inhibit their metabolism.

Inhibition of oral contraceptive steroid–metabolizing enzymes by steroids and drugs

F. Peter Guengerich, PhD
Nashville, Tennessee

The major 17α-ethinyl estradiol 2-hydroxylase is humans is the hepatic enzyme cytochrome P-450 IIIA4 (P-450NF), which is known to be inducible by rifampicin or barbiturates. The literature indicates that 17β-estradiol, progesterone, and norgestrel are competitive inhibitors and that primaquine and tolbutamide are rather weak noncompetitive inhibitors. Recent experiments in this laboratory indicate that gestodene is a relatively potent mechanism-based inactivator of cytochrome P-450 IIIA4 in vitro. Inhibition requires incubation with the reduced form of nicotinamide adenine dinucleotide phosphate, is time and concentration dependent, and can be partially blocked by the presence of noninhibitory cytochrome P-450 IIIA4 substrates. The in vitro activation by gestodene provides a possible explanation for the increase in plasma estrogen levels reported in women administered gestodene along with 17α-ethinyl estradiol. (Am J Obstet Gynecol 1990;163:2159-63.)

Key words: 17α-Ethinyl estradiol, 2-hydroxylation, gestodene, inhibition, of enzymes, cytochrome P-450 IIIA4

The main estrogenic component of oral contraceptives is 17α-ethinyl estradiol, which was introduced by Innhoffen and Hohlweg.[1] Its usefulness appears to result from its slow elimination relative to 17β-estradiol. Considerable variation is seen in the rates of clearance of ethinyl estradiol among women,[2-4] and such differences cause difficulty in adjusting the drug level. In addition to the normal variation seen among persons, another problem is introduced by the induction and inhibition of enzymes involved in the metabolism of ethinyl estradiol. 2-Hydroxy ethinyl estradiol, the major product, is also estrogenic but is not retained in the body as long as the parent compound. Menstrual problems and unexpected pregnancies have been experienced in some women using rifampicin or barbituates, and the effects can be rationalized in the decreased levels of ethinyl estradiol measured both in vivo and in vitro.[5-9] Bolt et al.[8] also demonstrated that rates of hydroxylation of estradiol were increased in women after treatment with rifampicin, with the effect presumably caused by enzyme induction.

Identification of cytochrome P-450$_{NF}$ as ethinyl estradiol 2-hydroxylase

Human liver P-450NF was first isolated as the enzyme catalyzing the oxidation of the calcium channel blocker nifedipine.[10] In that study the enzyme was also the principal catalyst in the main pathways of testosterone and estradiol metabolism in human liver, namely, 6β- and 2-hydroxylation, respectively. Further studies in this

Table I. Substrates for human liver cytochrome P-450 IIIA enzymes (P-450$_{NF}$)

Steroids	*Drugs*	*Carcinogens*
Testosterone (6β)	Nifedipine	Aflatoxin B_1
Estradiol (2,4)	Quinidine (3, *N*)	1,6-Dinitropyrene
Progesterone (6β)	Erythromycin	*tris*(Dibromopropyl)phosphate
Cortisol (6β)	Cyclosporine	6-Aminochrysene
Ethinyl estradiol (2)	Midazolam	Benzo*(a)*pyrene-7,8-diol

See Guengerich et al.,[10-12] Waxman et al.,[31] Shimada and Guengerich,[32] Shimada et al.,[33,34] Ged et al.,[35] and Guengerich[36] for original experiments and leading references.

and other laboratories have led to the assignment of this enzyme in a variety of other reactions involving the oxidation of steroids, drugs, and carcinogens (Table I).[11]

With the demonstration of the estradiol 2-hydroxylase activity of P-450NF and the suggestive evidence for induction of the enzyme by rifampicin (and the previous studies on rifampicin–ethinyl estradiol interactions[8]), the possibility was raised that P-450NF might be the human liver ethinyl estradiol 2-hydroxylase. Indeed such was the case; specific antibodies raised against P-450NF inhibited >90% of both the nifedipine oxidase and ethinyl estradiol 2-hydroxylase activities in human liver microsomes containing either high- or low-catalytic activity.[12] Rates of ethinyl estradiol 2-hydroxylation were well correlated with both rates of nifedipine oxidation and immunochemically determined P-450NF in liver samples obtained from different persons. Furthermore, troleandomycin (which has been shown to selectively inhibit cytochrome P-450 enzymes in the P-450 IIIA family)[13] was converted to a (nitroso) metabolite that blocked both nifedipine oxidation and ethinyl estradiol 2-hydroxylation. Several lines of evidence indicate that other cytochrome P-450 enzymes do not catalyze the reaction, including P-450DB (IID6), P-450PA (IA2), P-450$_j$ (IIE1), and the enzymes in the P-450 IIC family.[12]

It should be pointed out that P-450NF (IIIA4) is a member of a complex multigene family, with at least three proteins having >80% sequence identity.[14-16] The full details of specific expression and regulation of the genes are not understood at this time, and the possibility exists that more than one of these related proteins might contribute to ethinyl estradiol 2-hydroxylation and be recognized by the antibodies. Another point is that specific forms of cytochrome P-450 involved in ethinyl estradiol 2-hydroxylation in animal models have not been identified. If the 2-hydroxylation of estradiol can be used as a guide, then the rat model may be more complex. We previously reported that in contrast to the human liver, in which P-450NF is the principal catalyst of 2-hydroxylation, at least three cytochrome P-450 enzymes (the products of three different gene families) contribute to the reaction in the rat liver.[17]

Inhibitors of ethinyl estradiol hydroxylation

Purba et al.[18] examined several drugs and steroids for their ability to inhibit ethinyl estradiol 2-hydroxylation in vitro (in human microsomes, K_m 9 μmol/L). Several steroids were found to be competitive inhibitors, including estradiol (K_i 12 μmol/L), progesterone (K_i 69 μmol/L), and norgestrel (K_i 69 μmol/L). Primaquine and tolbutamide were noncompetitive inhibitors (K_i 69 μmol/L and 81 μmol/L, respectively). Several other compounds were tested and found to be rather poor inhibitors, including chloroquine, 1-methylimidazole, cholesterol, cortisol, diethylstilbesterol, antipyrine, mephenytoin, and metronidazole. Bolt and Kassel[19] reported that the insecticide synergist, 1-naphthyl-4(5)-imidazole, was a competitive inhibitor of microsomal ethinyl estradiol 2-hydroxylation (K_i 3 μmol/L) on the rat liver. Troleandomycin has already been shown to be an inhibitor of microsomal ethinyl estradiol 2-hydroxylation in vitro in the human liver.[12] Such macrolide antibiotics are known to be effective inhibitors in vivo[13] and one would also expect erythromycin to be a selective inhibitor of ethinyl estradiol 2-hydroxylation.

Mechanism-based inactivation by acetylenic steroids

In addition to the types of inhibition previously mentioned, mechanism-based or "suicide" inactivation of cytochrome P-450 is seen with the acetylenic steroids. White and Muller-Eberhard[20] reported that treatment of rats with ethinyl estradiol or norethindrone decreased the level of cytochrome P-450, and White[21] demonstrated the formation of green pigments formed from the heme of cytochrome P-450 in rats treated with ethinyl testosterone. Subsequently, the heme adducts formed by acetylenic steroids have been interpreted in terms of mechanism-based inactivation.[22-23] Mechanism-based enzyme inactivation is of significance in that only the enzyme involved in the biotransformation of the compound becomes inactivated, and the damage is therefore targeted.[24] Many of the acetylenic steroids appear to behave as inhibitors in this way.[25]

Although the chemistry of the green *N*-alkylporphyrins resulting from heme destruction has been deduced by Ortiz de Montellano et al., Davies et al.[26] have subsequently found that during the oxidation of norethindrone by rat liver microsomes, a considerable portion of the heme destroyed becomes irreversibly attached to the cytochrome P-450 apoprotein. The 2-hydroxy ethinyl estradiol that is formed by metabolism is readily oxidized in vitro to an ortho quinone that can covalently bind to protein,[9] but the significance of this reaction is unclear.

Ethinyl estradiol has been found to be a mechanism-based inactivator of human liver microsomal cytochrome P-450 and P-450NF (in vitro). The partition ratio, or number of times that an enzyme turns over a substrate before it is inactivated,[24] was estimated at ~120.[12]

Inhibition of cytochrome P-450 by acetylenic progestogens

Since progestogens are commonly used with ethinyl estradiol in contraceptive formulations, their interactions with estrogens are of great importance.[27] Kuhl et al.[28] reported that gestodene levels rise during therapy, and they considered the possibility that the increase was due to decreased metabolism. Furthermore, Kuhl et al.[28] found that in comparison with desogestrel, gestodene had a marked effect in increasing plasma levels of ethinyl estradiol, and they also showed that the cause was decreased clearance of the drug. In addition, cortisol levels were elevated in patients treated with gestodene, which might be expected if cytochrome P-450NF, the cortisol 6β-hydroxylase, was inhibited (Table I).

A series of 17α-acetylenic steroids was examined for the ability to inactivate human liver microsomal nifedipine oxidase and ethinyl estradiol 2-hydroxylase, activities of cytochrome P-450NF (Fig. 1). All the steroids proved to be inactivators, but clearly gestodene was the most effective when tested at the single concentration of 100 μmol/L. Indeed, the extent of inhibition seen with gestodene under these conditions was more marked than that found with a 20 μmol/L concentration of the classic inhibitor troleandomycin, which reduced the activity of nifedipine oxidase to 21% and that of ethinyl estradiol 2-hydroxylase to 65% under these conditions. The effects of gestodene were examined in more detail, the inhibition pattern is classic for mechanism-based inactivators[24] in that inactivation is first order in time and the rate increases with inhibitor concentration. The data can be used to derive the parameters K_i = 46 μmol/L and $k_{inactivation}$ = 0.39 minute.$^{-1}$ The $k_{inactivation}$ value is one of the highest ever measured for a microsomal cytochrome P-450 enzyme.[29]

In other studies it was possible to demonstrate the loss of spectrally detectable cytochrome P-450 in human liver microsomes during the oxidation of gestodene. In this particular sample, which is enriched with P-450NF, the level of cytochrome P-450 was decreased to 40% and thereafter remained constant. The difference in the rates of destruction of cytochrome P-450 by gestodene and ethinyl estradiol is quite dramatic, and logarithmic plots indicate that the rate is approximately 50-fold greater in the case of gestodene.

Gestodene was effective in destroying microsomal cytochrome P-450, even at the lower concentration of 10

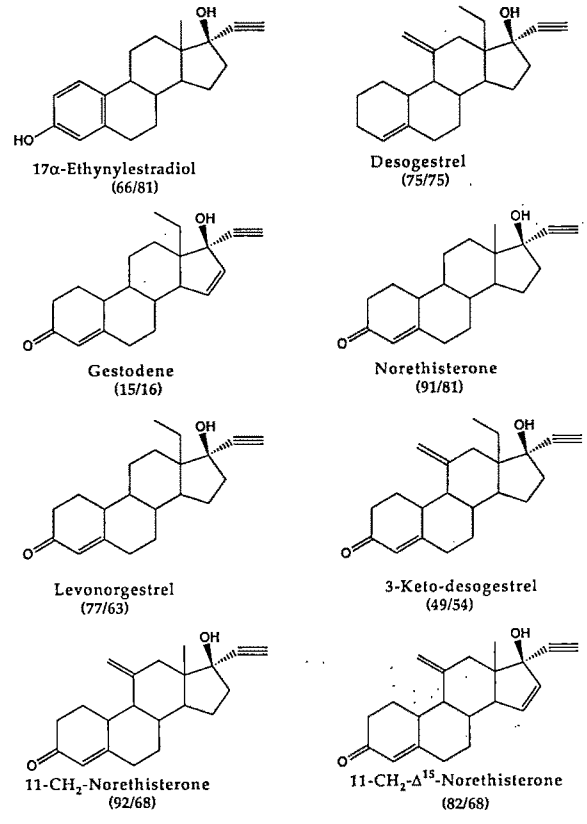

Fig. 1. Structures of synthetic 17α-ethynyl and 17β-hydroxy steroids examined as mechanism-based inactivators of human liver microsomal cytochrome P-450. Each steroid (100 μmol/L) was incubated with 250 pmol of human liver cytochrome P-450 (liver sample HL 110) and an NADPH-generating system in a reaction volume of 50 μl at 37° C for 30 minutes. At that time the reaction was diluted to a volume of 1.0 ml with the NADPH-generating system and either 200 μmol/L nifedipine or 100 μmol/L 17α-ethinyl estradiol, and these incubations proceeded for an additional 10 minutes. Rates of nifedipine oxidation and 17α-ethinyl estradiol 2-hydroxylation were determined by high-performance liquid chromotagraphy and rates of the activities relative to those measured in similar experiments without steroids are presented (as percentages of uninhibited values). The first of each pair of numbers *(in parentheses)* indicates the relative rate of nifedipine oxidation, and the second indicates the relative rate of ethinyl estradiol 2-hydroxylation. *NADPH*, Nicotinamide adenine dinucleotide phosphate.

μmol/L (57% ± 4% cytochrome P-450 remaining after 10 minutes). The destruction could be partially blocked by high concentrations of the P-450NF substrates quinidine (100 μmol/L, 76% ± 1% original cytochrome P-450 after 10 minutes) and nifedipine (200 μmol/L, 82% ± 4% original cytochrome P-450 remaining after 10 minutes). The K_m values for quinidine and nifedipine are 4 and 19 μmol/L, respectively.[10,11] Comparison of the rates of nifedipine oxidase inactivation and gestodene disappearance (at a single concentration of gestodene) yields an estimated partition ratio of 9 gestodene, which can be compared with the value of 120 for ethinyl estradiol.[12] Therefore a given dose of gestodene

would be expected to inactivate 15 times as much cytochrome P-450NF as does ethinyl estradiol.

More than 10 gestodene metabolites are known,[27] with biotransformation resulting from the formation of the 3α- and 3β-hydroxyl compounds, 4, 5-hydrogenation, hydroxylation at the 1, 6α, 11 and other unidentified positions, and homoannulation (conversion of the D ring to a cyclohexanone with release of CO_2).[30] It is somewhat surprising that a 6β-hydroxy product has not been identified, since 6β-hydroxylation is observed in the cytochrome P-450NF oxidations of the Δ^4 3-keto steroids testosterone, androstenedione, cortisol, and progesterone.

Conclusions

P-450NF (and possibly closely-related enzymes) is the major catalyst involved in the 2-hydroxylation of ethinyl estradiol, the major step in the clearance of the compound in the human liver. The enzyme appears to be induced by the administration of rifampicin, barbiturates, or certain steroids such as dexamethasone. The enzyme catalyzes the oxidation of several steroids, drugs, and carcinogens (Table I), and variations in the activity of the enzyme would alter the rates of biotransformation of all these compounds. Most of the inhibitors of the enzyme require metabolism to exert their effects. All 17α-acetylenic steroids examined are mechanism-based inactivators of P-450NF and its activities, but gestodene shows a remarkably high activity in this regard. This property of the compound can explain its ability to elevate plasma levels of ethinyl estradiol and cortisol. Examination of the effects of the different steroids tested does not permit elucidation of the structure/function relationships related to mechanism-based inactivation of P-450NF. Because the inhibition seen with gestodene is mechanism based, only those cytochrome P-450–mediated activities associated with P-450NF (Table I) would expected to be compromised in patients receiving the drug. Finally, gestodene appears to be an excellent compound to be used in the further in vitro and possibly in vivo examination of which compounds are oxidized by cytochrome P-450NF.

Formation, metabolism, and physiologic importance of catecholestrogens

Peter Ball, Prof. Dr. med,[a] and Rudolf Knuppen, Prof. Dr. Rer. Nat.[b]
Lübeck, West Germany

The metabolism of natural and synthetic estrogens is governed primarily by hydroxylations, leading to polyhydroxylated derivatives of the steroid molecule. In mammals aromatic hydroxylation is most prominent quantitatively. The 2- and 4-hydroxyestrogens (catecholestrogens) formed are secreted not only in high amounts in urine but are also present in significant quantities in different organs, such as the liver, pituitary gland, and hypothalamus. This A ring hydroxylation of primary estrogens is affected by peroxidases, tyrosinases, and unspecific monooxygenases by mechanisms still not completely understood. The activity of the aromatic hydroxylases is regulated not only with respect to the overall extent but also to the relative rate of hydroxylation at C-atoms 2 and 4. The metabolism of catecholestrogens may be divided into reversible and irreversible reactions, of which the reaction with the catechol-O-methyltransferase, and thereby the interaction with catecholamines, the conjugation, and the thioether formation are the most prominent. Low- and high-affinity binding is operative in binding to plasma proteins and receptors. Finally, irreversible binding to cellular macromolecules, such as proteins and deoxyribonucleic acid, and the oncogenic potential of natural and synthetic catecholestrogens are discussed. (Am J Obstet Gynecol 1990;163:2163-70.)

in addition to conjugation, are essentially transformed by hydroxylation reactions. In mammals these hydroxylations occur not only at the aliphatic C-atoms 18, 16, 15, 14, 11, 7, and 6, but also at aromatic positions 4 and 2. This aromatic ortho-hydroxylation of phenols, also well known in the biotransformation of many nonsteroidal compounds with physiologic and pharmacologic importance, has several interesting features that stimulated intense and steadily increasing investigations into 2- and 4-hydroxyestrogens in recent years.

Because of the evident structural relationship between E_2, ethinyl estradiol (EE), and in part tyrosine, the reactions given here for the natural estrogens are, in general, the same for all phenols.

Metabolism of E_2 in vitro in rat and human liver and in vivo in humans[1, 2]

When [6,7-^{3}H]E_2 is incubated with rat liver slices for 1 hour under O_2, approximately 50% of the radioactivity remains lipophilic, 30% becomes water soluble, and 4% is irreversibly bound to protein.

In the water-soluble fraction containing the "classic" conjugates, conjugates with sulfuric and glucuronic acid, and the "newer" conjugates, mainly glutathione, the sulfate esters predominate. Within the more than 20 metabolites isolated from the lipophilic and, after hydrolysis, water-soluble fractions of rat liver, the main metabolites are 2-hydroxylated estrogens (25%), followed by their isomeric monomethyl ethers (15%), 4-hydroxyestrogens are of minor importance (8%).

Essentially the same distribution pattern of metabolites is found on incubation of human liver slices, although the turnover of the substrate is reduced.

In the same patient whose in vitro metabolism in the liver was explored, [4-^{14}C]E_2 was administered orally, and the excretion pattern of radioactive metabolites was monitored in urine. Again, 2-substituted estrogens were the main products (10%), although they did not exceed the sum of primary (E_1 + E_2 = 8%) and 16α-hydroxylated (16α-OHE$_1$ and E_3 = 6%) estrogens.

Concentrations of endogenous 2-substituted estrogens in tissue, blood, and urine

Using a monoisotope-derivative method (radioenzymatic assay) and ether extracts of the tissues, preliminary values for the concentration of 2-hydroxyestrone (2-OHE$_1$) in the female rat were 560 pg/gm for the liver, 770 pg/gm for the pituitary gland, and 150 pg/gm for hypothalamic tissue. In comparison, rat plasma contained about 520 pg/ml.[3]

With the use of newly developed radioimmunoassays for all relevant catecholestrogens, the determination of plasma concentrations became feasible. The obtained normal values in humans are given in Table I.[3, 4] Unconjugated and conjugated steroids were determined separately. The 2-OHE$_1$ concentrations were in the range of those of E_1, and the 2-OHE$_1$ 2-methyl ether (2-OCE$_1$) concentrations were even slightly higher than those of E_1 and 2-OHE$_1$ together. Determinations of the conjugated 2-OHE$_1$ and 2-OCE$_1$ concentrations resulted in 10 to 20 times higher values than those obtained for the unconjugated steroids.

Using the same radioimmunoassays, urinary excretion rates of 2-substituted and 4-substituted estrogens were monitored.[3] The results for the 2-substituted estrogens are given in Table II. Of special interest were the molar ratios of 2-substituted to 2-nonsubstituted estrogens, the so-called total estrogens. With the exception of women in the reproductive phase, the amount of 2-substituted estrogens clearly surpassed the

amount of all other estrogens together. For the excretion rates of 2-OHE_1 and 4-OHE_1 during the menstrual cycle of four healthy subjects, see ref. 4.

Formation of catecholestrogens: Enzymatic hydroxylation of estrogens

Enzymatic A ring hydroxylation of primary estrogens is thought to be affected by three different hydroxylating systems: peroxidases, tyrosinases, and the "unspecific monooxygenases."

The mechanism of action of these three enzymes is still poorly understood. It is strongly interconnected with glutathione metabolism and thus thioether formation.[5] It is believed that peroxidases, through the generation of hydroxyl radicals, initially oxidize phenols to phenoxy radicals, eventually leading to dihydroxybenzenes (catechols), partly in a semiquinone or o-quinone–reactive form (Fig. 1). These quinones show a high binding to deoxyribonucleic acid and protein, a reaction that may be competitively inhibited by glutathione (GS-SG and thioether formation) and lipids (lipid peroxidation).[3] Recently, the estrogen 2-/4-hydroxylase activity of the soluble fraction of human breast cancer tissue was found to behave similarly to the peroxidase type from the rat uterus.[6]

Tyrosinases that show both phenol o-hydroxylase and catechol oxidase activity catalyze a two-electron transfer to form o-quinones (Fig. 2). The quinones have the remarkable ability to conjugate with reactive groups on the tyrosinase molecule itself and thus have the potential to inhibit the further action of the enzyme (product inhibition from the suicide type). The addition of glutathione enhances tyrosinase activity, presumably by protecting functional groups of the enzyme or reactive groups of the product, thereby inhibiting the suicide reaction by enhancing not only thioether conjugation but also the formation of protein adducts. Similar reactions were observed with EE and dopa as substrates.[5]

However, the classic estrogen 2-/4-hydroxylase seems

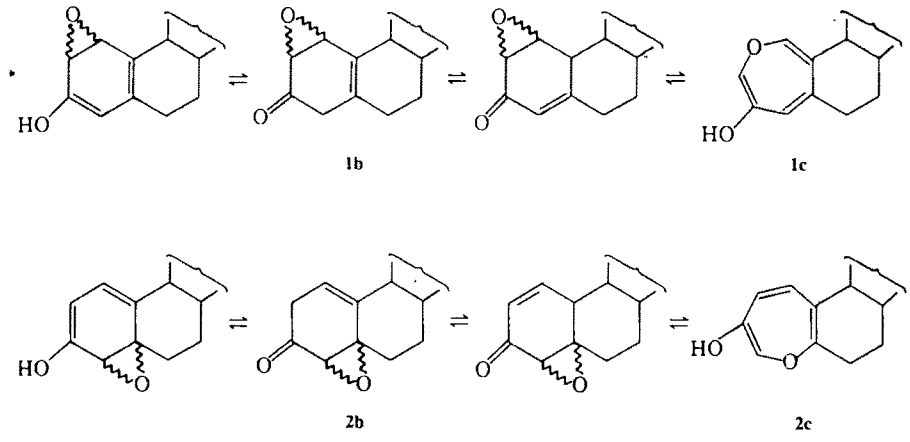

Fig. 3. Hypothetic intermediates in the biosynthesis of 2- and 4-hydroxyestrogens. (From Kuss E. Estrogens and glutathione. In: Dolphin D, Voulson R, Avramovic O, eds. Glutathione. New York: John Wiley & Sons, 1989:512-49. Copyright© 1989 by John Wiley & Sons, Inc. Reprinted by permission of John Wiley & Sons, Inc.)

to be a cytochrome P-450–dependent microsomal enzyme system. The labile 1,2- and 4,5-arenoxides (dienol epoxides) (Fig. 3), in equilibrium with the more stable keto- and oxepin tautomers, are the postulated intermediates. Arenoxides are unlikely precursors of thioethers, which need an o-quinone, or more likely a semiquinone radical, as molecular species immediately preceding their formation.[5]

Hydroxylase activity is strongly dependent on the nature of the substrate: 17α-EE is a far better substrate than are natural estrogens (EE > E_2 > E_1).

Enzymatic activity is increased by higher age and the male sex—androgens and castration[7]—and a widely varying array of substances such as phenobarbital,[5] EE,[8] and rifampicin,[9, 10] and decreased by cytochrome P-450 inhibitors,[5] 2- and 4-haloestrogens,[11] and growth hormone.[12] Finally, urinary excretion of 2-hydroxyestrogens was increased by malnutrition, hyperthyroidism, and tobacco smoking and decreased by liver cirrhosis.[3, 5] Because the C-2 and C-4 hydroxylations are strongy correlated (ratio of activity 10:1 to 20:1), the same mechanism seems to be operative in both reactions. Nevertheless, the relative C-2/C-4 reaction rates vary depending on both the substrate and the source of the enzyme.[1, 13]

Metabolism and binding of catecholestrogens

To elucidate the importance of catecholestrogens in physiology, the rate of formation is one important parameter; the metabolism and binding are others. Within the latter we must discriminate between enzymatic (nonenzymatic) metabolism of the catecholestrogens, both reversible and irreversible, and low- and high-affinity binding, with functional preservation of the catechol structure.

One of the reversible interactions is the reaction with enzymes such as the catechol-O-methyltransferase (COMT). In 1958 Axelrod and Tomchick[14] already showed that the COMT is one of the key enzymes in the metabolism of catecholamines. We purified the enzyme from the liver, characterized it, and proved Knuppen's hypothesis[15] that the enzymatic methylation of 2-hydroxyestrogens and catecholamines is accomplished by the same methyltransferase.[16] Moreover, we showed that under standard assay conditions, catecholestrogens were not only the preferred substrates (Table III)[17], but also the most potent inhibitors of the methylation of catecholamines in vitro (Fig. 4).[18-20] We suggested that the inhibition of catecholamine metabolism by the catecholestrogens might cause prolongation and potentiation of the physiologic actions of the catecholamines, especially blood pressure and gonadotropin release.[21]

As demonstrated already by Axelrod and Tomchick, COMT is an ubiquitous enzyme. Of special interest is its high activity in red blood cells,[22] which leads to the high plasma metabolic clearance rate of catecholestrogens (Table IV)[23] and falsely low catecholestrogen concentrations if the blood is handled incorrectly.[22] Catecholestrogens monomethyl ethers are prone to extensive demethylation. On incubation with rat liver slices, apparent Kms of 12 and 3 μmol/L for 2-OCE_1 and 2-OCE_2 were obtained.[17]

Catecholestrogens are metabolized by two other reversible reactions: conjugation with glucuronic and sulfuric acid on incubation of [4-^{14}C]2-OHE_2 or [4-^{14}C]E_2 with rat liver slices; the most prominent finding is the extensive conjugation of the catecholestrogens,[24] a conjugation rate that is significantly higher (58%) than that of the primary estrogen (47%).

Finally, two irreversible reactions of catecholestrogens should be mentioned. It has long been known that

Table III. Substrate specificity of COMT from human liver

Substrate	*K_m (μmol/L)*

rat liver homogenates metabolize monophenolic estrogens to water-soluble metabolites that are not glucuronides or sulfates.[25] One possibility is that the further hydroxylation of catecholestrogens leads to tetrahydroxylated, highly water-soluble compounds; another possibility is the irreversible binding to amino acids and proteins, including the formation of thioethers.

With respect to thioether formation, Jellinck et al.[26] and Kuss[27] observed that rat liver microsomes in the presence of the soluble fraction[26] or a rat liver homogenate[27] transformed E_2 to metabolites that had the characteristics of both a peptide and a phenolic steroid. The isolated products were mainly glutathione conjugates coupled with the steroid by a carbon-sulfur linkage, predominantly at C-atom 4 (ratio of the 4- to the 1-S isomer approximately 3 : 1). Because the same products were also formed when microsomes or homogenate were completely omitted, a spontaneous nonenzymatic process (the addition of thiol by redox reactions) was assumed (Fig. 5), and it was stated that the semiquinone radical of catecholestrogens seems to be the molecular species immediately preceding the thioether.[5] Moreover, because the in vivo formation of thioethers was never shown,[5] it was concluded that "activated estrogens," capable of reacting spontaneously with glutathione, are formed only in very artificial systems.[5]

Carcinogenesis and cell damage hypothetically induced by estrogens, especially EE_2 and diethylstilbestrol,[28] have been proposed to be mediated by activated catecholestrogen metabolites[29-33]; activated catecholestrogens are known to react covalently with protein and nucleic acids. However, the mechanism of interaction remains obscure: sulfydryl groups as acceptors have been excluded, whereas catecholestrogen-protein thioethers have not been found.[5] Thus amino groups of nucleic acid bases or proteins may react with catecholestrogen quinones. Glutathione, ascorbic acid, and lipids are thought to compete with macromolecular binding, thus possibly preventing some of the deleterious effects of catecholestrogens.[5]

I now come to binding, with functional preservation of the catechol structure, that is, binding to receptor and plasma proteins.

Aside from production and metabolism, the availability of steroids is determined by their binding to plasma proteins. In humans steroid hormones circulate in complex with three major plasma proteins: sex hormone–binding globulin, cortisol-binding globulin, and albumin.[34] Although the relative binding to the three proteins varies widely from steroid to steroid, sex hormone–binding globulin is the most important binding protein. The relative binding affinities given in Table V show a striking affinity of 2-OCE_2 that exceeds that of E_2 by a factor of 4, whereas the relative binding affinity of catecholestrogens amounts to about 1% of that value.

The finding that 2-methylated catecholestrogens bind to sex hormone–binding globulin with high affinity in vitro and that sex hormone–binding globulin is the major transport protein for sex steroids in vivo

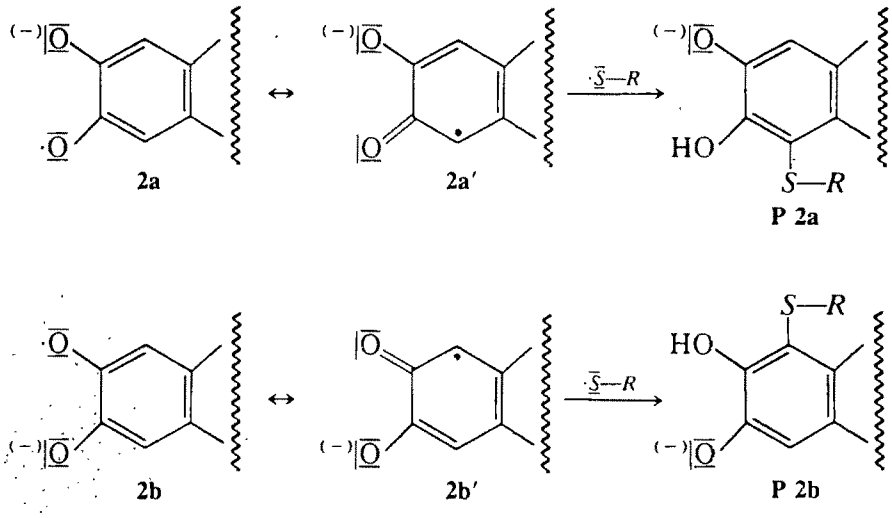

Fig. 5. Proposed mechanism of thioether formation. (From Kuss E. Estrogens and glutathione. In: Dolphin D, Voulson R, Avramovic O, eds. Glutathione. New York: John Wiley & Sons, 1989:512-49. Copyright© 1989 by John Wiley & Sons, Inc. Reprinted by permissions of John Wiley & Sons, Inc.)

Table V. Relative binding affinities of 2- and 4-substituted estrogens to sex-hormone–binding globulin (testosterone = 1000)

Testosterone	1000
2-OCE_1	750
Estradiol	500
2-OHE_2	7

raises the possibility that compounds that have negligible sex hormone activity could exert physiologically important effects by altering the transport of other endogenous sex hormones. With a computer model, the tremendous impact of increasing 2-OCE_1 concentrations on free E_2 and testosterone concentrations was calculated.[34]

Assuming that catecholestrogens bind to the same receptor as E_2, Martucci and Fishman[35] examined the relative binding affinities of a series of 2- and 4-hydroxylated estrogens compared with E_2. In the crude uterine receptor preparation used, that is, 120,000 *g* supernatant of rat uterus homogenate, the percentages shown in Table VI were obtained.

To evaluate the biologic significance of these binding affinities, some further investigations must be mentioned.[3] Comparing the biologic potencies after short-term injection with these relative binding affinities, the following relationships have been found: 2-OHE_1 has 20% of the relative binding of E_1 but only 0.1% of its estrogenic potency (ratio 1:200), and 4-OHE_2 has 50% of the relative binding of E_2 but only 10% of its estrogenic potency (ratio 1:5). The reasons for these discrepancies are as follows: (1) 2-OHE_1 is more intensely metabolized than is 4-OHE_2 and especially E_2, thus preventing comparable amounts of the steroid ever to reach the receptor in vivo.[3] (2) Assuming that catechol estrogens might act analogous to E_3, in vivo dissociation rates were examined. As anticipated, 2-hydroxylation resulted in an increase, but 4-hydroxylation resulted in a decrease in dissociation rates compared with the parent estrogen. Consequently, an interesting experiment was done.[36] In an attempt to minimize the effects of differences in the rates of metabolism, two successive injections of estrogens in doses adjusted to give similar nuclear estrogen receptor concentrations were applied to living rats and the biologic effect (concentrations of the cytoplasmic progestin receptor in the rat pituitary gland) was monitored (Table VII). Strikingly, 2-OHE_2 was about one half less, but 4-OHE_2 was about one half more potent than the parent E_2.

In conclusion, on continous administration, differences in metabolism, receptor binding, receptor kinetics, and biologic responses lead to a much smaller biologic (estrogenic) effect of 2-hydroxyestrogens but to about an equal effect of E_2 and 4-OHE_2.

Interactions of catecholestrogens (especially EE) with catecholamines, proteins, and deoxyribonucleic acid

In general, it may be stated that the production and endogenous metabolism of estrogens are strongly interconnected with the metabolism and biologic effects of other chemically related endogenous and exogenous substances.

From the literature it is known that the biologic effects of catecholamines are governed not only by enzymatic formation (key enzyme: tyrosinase), enzymatic inactivation (COMT/monoamine oxidase), and ultimate receptor binding, but also by the reuptake of

Table VI. Relative binding affinities of estrogens to the cytosolic receptor (percent)

CA receptors	E_2 > 2-OHE_2

CA, Catecholamine; *NE*, norepinephrine.

catecholamines into the cell. EE could possibly interact with all four events.

Without discussing the details of the investigations reported so far, the following may be summarized[37] (Table VIII): the interference of E_2 and 2-OHE_2 with the catecholamine receptor is at least questionable.

Catecholestrogens as catecholamines are approximately equal potent inhibitors of tyrosinase activity. However, because high concentrations of catecholestrogens are necessary to cause measurable inhibition, the physiologic role of this interaction remains uncertain.

Although in vitro catecholestrogens and especially 2-OHEE are potent inhibitors of the COMT-mediated inactivation of catecholamines, this inhibiton with its proved prolongation of catecholamine action does not seem essential for the regulation of blood pressure in vivo. As suggested by Ghraf and Hiemke,[37] the reuptake inhibition brought about by E_2 and 2-OHE_2 may be the dominant mechanism.

17α-EE is a potent inhibitor of catecholamine reuptake. The introduction of a 2-hydroxy- and especially the 4-hydroxy group, however, reduces the inhibitory potency.

In conclusion, it may be stated that EE, together with its ortho-hydroxylated metabolites (2-OHEE and 4-OHEE), increases the biologic activity of catecholamines more than the primary estrogens, an effect that may be enhanced even during high catecholamine secretion states, such as under the influence of stress caused by physical activity.[38]

Another possibly adverse effect of the highly effective synthetic estrogen compared with primary estrogens may stem from its more rapid metabolism to catechol derivatives, with the potential of irreversible binding to cellular macromolecules such as proteins and deoxyribonucleic acid. It is interesting to note that the oncogenic potential of an estrogen seems to be related to its relative rate of conversion to a catecholestrogen and not to its estrogenic potency per se.[39] Although controversial in the literature,[28] high concentrations of estrogens, but especially of EE, present over a long time interval may eventually facilitate the development of cancer, especially uterine and breast cancers.

SESSION IV. HORMONAL EFFECTIVENESS OF ORAL CONTRACEPTIVE STEROIDS

Chairman: M. Breckwoldt

Binding of oral contraceptive progestogens to serum proteins and cytoplasmic receptor

Michael Juchem* and Kunhard Pollow, MD, PhD
Mainz, West Germany

Some progestogens widely used in oral contraceptives are characterized at the level of high-affinity receptor binding as well as binding to sex hormone–binding globulin and corticosteroid-binding globulin. With regard to binding to sex hormone–binding globulin, gestodene, levonorgestrel, and to a lesser extent 3-ketodesogestrel (which is only formed from the prodrug desogestrel in the body), show a behavior that is manifested in the relatively high affinity to sex hormone–binding globulin, whereas desogestrel and norgestimate do not display any measurable affinity for this specific steroid-binding serum protein. Furthermore, levonorgestrel and gestodene dissociate very much more slowly from the binding sites of sex hormone–binding globulin than 3-ketodesogestrel. A natural affinity of all these synthetic progestogens tested for corticosteroid-binding globulin could not be established. Gestodene, levonorgestrel, and 3-ketodesogestrel bind to the progesterone, glucocorticoid, and androgen receptor with high affinity, apart from slight differences, whereas estrogen receptor affinity could not be demonstrated in any of the progestogens investigated. In relation to aldosterone, the relative binding affinity values of gestodene, levonorgestrel, and the natural progestogen progesterone are relatively high, whereas 3-ketodesogestrel does not display any measurable affinity for this receptor species. (Am J Obstet Gynecol 1990;163: 2171-83.)

Key words: Sex hormone–binding globulin, competition studies, steroid receptors, gestodene, desogestrel, levonorgestrel, norgestimate

A generally accepted classical principle of therapy with pharmacologically active substances is that the greatest possible effectiveness is to be reached at the lowest dosage. The idea behind this approach is based on the assumption that the lower the therapeutic dose, the less the burden on the body as a whole, especially in terms of possible adverse drug effects.

With regard to oral contraceptives, efforts have been made over many years to reduce the overall amount of estrogenically and progestogenically active steroid components applied over the menstrual cycle and to find synthetic steroids that offer not only efficacy but also a large measure of tolerance.

The proportion of estrogen in the oral contraceptives of the most recent generation has been reduced; for example, it is down to 30 μg per pill in the most widespread form of ethinyl estradiol, above all to lower markedly the incidence of adverse drug effects caused by estrogens. Regarding the gestagen constituent in oral contraceptives, however, there is no uniformity with regard to the steroid used or to the dosage. The synthetic progestogens most frequently used are levonorgestrel, desogestrel, gestodene, cyproterone acetate, and norgestimate. Thus levonorgestrel, the classic orally active synthetic progestogen, presents the advantage of balancing overshoot and adverse effects of the estrogen component besides providing a markedly reduced dosage.[1] The antiandrogenically active cyproterone acetate had the advantage of processing a highly antiandrogenic activity component, in addition to its potent gestagenic effects, which allowed an additional effective treatment in androgenization manifestations of the skin in potential users of oral contraceptives.[2-5] Desogestrel,[6-9] gestodene,[10-13] and norgestimate,[14] further agents from the 19-nortestosterone series, which are now available for clinical application in oral contraceptives, appeared to set new standards with regard to activities and hormonal profiles.

The dosage of progestogens used in oral contraceptives shows a large range of variation. However, a dose reduction of a certain progestogen is limited by its hormonal effectiveness, because the component used in oral contraceptives has to suppress ovulation reliably.

Table I. Relative binding affinities (%) of various progestogens in comparison with cortisol and DHT for binding to human CBG and SHBG

	CGB	*SHBG*
Cortisol	100	<0.1
DHT	<0.1	100
Progesterone	53	<0.1
Medroxyprogesterone acetate	<0.1	<0.1
Cyproterone acetate	<0.1	<0.1
Org2058	<0.1	<0.1
R5020	<0.1	<0.1
Levonorgestrel	<0.1	50
Gestodene	<0.1	40
3-Ketodesogestrel	<0.1	5
Desogestrel	<0.1	<0.1
Norgestimate	<0.1	<0.1

Therefore, a progestogen used in a lower dose must be more potent, not only with respect to central effects, but also in regard to peripheral effects.

The efficacy of the progestogen used is a feature consisting of a kaleidoscope of the most different qualities. According to the conventional view, a basic prerequisite for gestagenic activity is an adequate affinity for the progesterone receptor and active induction of a conformational change of the receptor molecule during binding as well as the duration of binding to the chromatin. Whereas the affinity of a progestogen to the receptor is a parameter determined by the structure of the steroid, the number of the receptors occupied by the steroids depends on the steroid concentration in the target cell. The intracellular steroid level is in turn a function of the "free" steroid, which is only able to enter the cell, but which is also dependent on intracellular metabolism and storage. The blood level of "free" steroid, that is, nonprotein-bound steroid, is mainly influenced by the total steroid level and by the affinity to specific steroid-binding proteins such as sex hormone–binding globulin (SHBG) or corticosteroid-binding globulin (CBG).

The blood levels also depend on absorption, metabolism in the gastrointestinal tract and in the liver, distribution and storage in the tissues, the enterohepatic circulation, and the rate of elimination and excretion-dependent function, that is, the pharmacokinetics. The dosage of progestogens in oral contraceptives is thus only one link in the long chain that ultimately determines the efficacy of a steroid hormone.

The aim of the present study is to make a broad characterization of progestogens such as levonorgestrel, desogestrel, gestodene, and norgestimate,[1-14] which are widely used in oral contraceptives, at the level of receptors and as high-affinity steroid-binding serum proteins.

Material and methods

Materials. Tritiated aldosterone (specific activity 2.96 terabecquerel [TBq]/mmol), tritiated R5020 (specific activity 3.22 TBq/mmol), tritiated DHT (specific activity 5.29 TBq/mmol), tritiated estradiol (specific activity 3.44 TBq/mmol), tritiated R1881 (methyltrienolone) (specific activity 3.22 TBq/mmol), and tritiated unlabeled R5020 and R1881 were purchased from New England Nuclear, Dreieich, West Germany. Tritiated dexamethasone (specific activity 3.03 TBq/mmol), tritiated Org2058 (specific activity 2.2 TBq/mmol), and tritiated cortisol (specific activity 3.6 TBq/mmol) were obtained from Amersham Buchler, Braunschweig, West Germany. Tritiated gestogene (specific activity 2.0 TBq/mmol), tritiated 3-ketodesogestrel (specific activity 1.6 TBq/mmol), tritiated levonorgestrel (specific activity 1.8 TBq/mmol), and unlabeled gestodene, desogestrel, 3-ketodesogestrel, norgestimate and levonorgestrel were a gift from Schering AG, Berlin-Bergkamen, West Germany. Other steroids used were ordered from Serva, Heidelberg, West Germany. All other chemicals were of pharmaceutical grade. PENG-buffer consisted of 10 mmol/L KH_2PO_4, 10 mmol/L K_2HPO_4, 1.5 mmol/L EDTA, 3 mmol/L NaN_3, 5 mmol/L monothioglycerol, and 10% glycerol, pH 7.5. DCC (dextran-coated charcoal) consisted of 0.5% Norit A and 0.05% dextran T400 in PENG-buffer.

Tissues and serum samples. Kidneys of adrenalectomized female Wistar rats were used as a source for mineralocorticoid receptor. Estrogen and progesterone receptors were assayed in cytosols of human uterine tissues. Glucocorticoid receptors were determined in cytosols of adrenalectomized female Wistar rat livers. The binding of steroids toward androgen receptors was determined in the cytosol of prostates of castrated rats.

For binding analysis to the serum steroid-binding proteins (CBG and SHBG), human pregnancy serum that was stripped of endogenous steroids with dextran-coated charcoal was used. All tissues and serum samples were quick-frozen in liquid nitrogen and stored at −80° C until use.

Cytosol preparation. The frozen tissue samples were minced, and after the addition of cold PENG-buffer, were homogenized (Ultra Turrax; Janke und Kunkel, Melsungen, West Germany).

The homogenate was centrifuged at 105,000 *g* at 4° C for 30 minutes in a fixed-angle rotor (60 Ti; Beckman Instruments, Munich, West Germany). The clear supernatant was used. Protein concentrations of the cytosols were determined according to the method of Lowry et al.[15]

Relative binding affinities

MINERALOCORTICOID RECEPTORS. Aliquots (0.1 ml) of rat kidney cytosols were incubated with tritiated al-

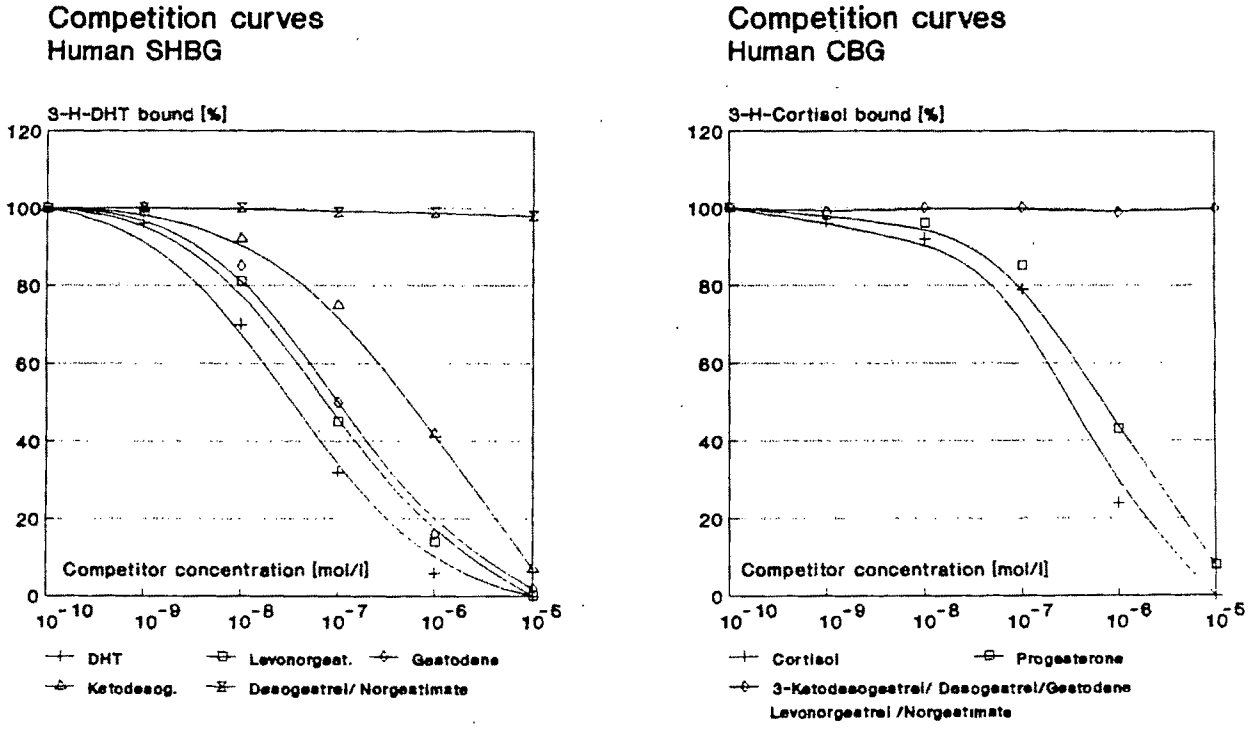

Fig. 1. Competition for labeled DHT and cortisol binding in diluted serum of pregnant women.

dosterone (50 μl, final concentration 8 nmol/L), together with increasing concentrations (50 μl, final concentration 10^{-10} to 10^{-5} mol/L) of various competitor steroids for 4 hours at 4° C in the presence of a 200-fold molar excess of nonlabeled RU 28362. Unbound steroids were adsorbed by incubating with 0.5 ml of a dextran-coated charcoal suspension for 10 minutes at 4° C. After centrifugation (10 minutes, 1500 *g*, 4° C), 0.5 ml of the supernatant was withdrawn and counted for radioactivity. The relative binding affinities were evaluated according to the method of Korenman.[16]

GLUCOCORTICOID RECEPTORS. Cytosols of livers of adrenalectomized rats were used, and tritiated dexamethasone (final concentration 8 nmol/L) served as ligand. The incubation period was 4 hours at 4° C.

PROGESTERONE RECEPTORS. For cytosol preparation, human uterine tissues were used; tritiated R5020 (final concentration 8 nmol/L) served as ligand. The incubation period was overnight at 4° C.

ESTROGEN RECEPTORS. Cytosol was prepared from human uterine tissues; the ligand was tritiated estradiol (final concentration 8 nmol/L). The incubation period was overnight at 4° C.

ANDROGEN RECEPTORS. Progesterone receptor-free cytosols of prostates of castrated rats were used; tritiated R1881 (final concentration 8 nmol/L) served as ligand in the presence of a 200-fold molar excess of unlabeled triamcinolone acetonide. The incubation period was 4 hours at 4° C.

SERUM BINDING PROTEINS. Relative binding affinities toward SHBG and CBG were determined by using stripped human pregnancy serum in a dilution with PENG-buffer in a ratio of 1:50 and tritiated cortisol or tritiated DHT as ligands, both in a final concentration of 8 nmol/L. The incubation period was overnight at 4° C.

Rate of association of tritium-labeled progestins with serum proteins. Aliquots (0.1 ml) of diluted serum from pregnant women or purified SHBG were incubated in triplicate with different tritium-labeled progestins (final concentration 8 nmol/L), either alone (total binding) or together with a 200-fold molar excess of unlabeled identical progestin at 4° C for different time intervals as indicated in the Figures. At the time intervals indicated, 0.5 ml dextran-coated charcoal suspension was added and incubated for 10 minutes. After centrifugation (10 minutes, 1500 *g* 4° C), 0.5 ml of the supernatant was withdrawn and counted for radioactivity.

Rate of dissociation of different tritium-labeled progestins from serum proteins. Aliquots (0.1 ml) of diluted serum from pregnant women, or purified SHBG and CBG, were incubated in triplicate with tritium-labeled progestins (final concentration 8 nmol/L) plus or minus a 200-fold molar excess of unlabeled identical progestin overnight at 4° C. To all tubes 0.5 ml of dextran-coated charcoal was added and incubated for different time intervals, as indicated in the Figures, under gentle shaking at 4° C. After the

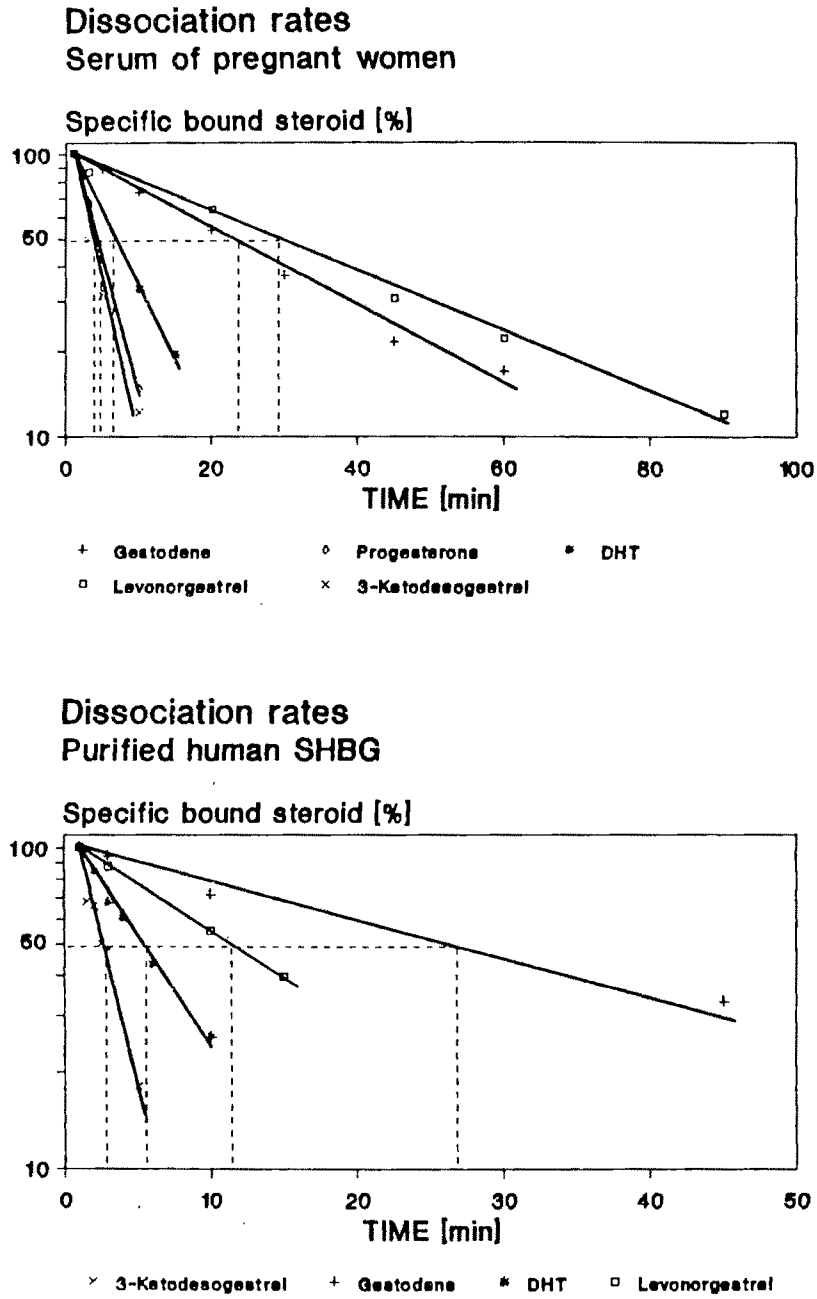

Fig. 2. Determination of the half-life of various tritium-labeled steroid-binding complexes of diluted serum of pregnant women and purified human SHBG.

time intervals indicated, the tubes were centrifuged (10 minutes, 1500 *g*, 4° C), and 0.5 ml of the supernatant was counted for radioactivity.

Titration analyses. The general set-up was as follows: 0.1 ml aliquots of aqueous tritiated steroid solutions (final concentrations 0.5, 1.0, 2.0, 4.0, and 8.0 nmol/L) were incubated either alone (total binding, duplicates) or together with a 200-fold molar excess of unlabeled competitor (nonspecific binding), together with 0.1 ml of diluted serum of pregnant women for 4 hours at 4° C. Dextran-coated charcoal (0.5 ml) was added, incubated for 10 minutes or only 5 minutes at 4° C and centrifuged for 10 minutes at 1500 *g* and 4° C. Aliquots (0.5 ml) of the supernatants were withdrawn and counted for radioactivity. The binding data were calculated according to the method of Scatchard.[17]

Sucrose density gradient analysis. Aliquots of 0.5 ml of human uterine cytosol were incubated with 16 nmol/L of tritium-labeled steroids with or without a 200-fold molar excess of unlabeled steroids for 16

hours at 4° C. After that, unbound steroids were then removed by DCC treatment and 0.2 ml aliquots were layered on top of 10% to 35% linear sucrose gradients. The gradients were centrifuged for 2.5 hours at 4° C at 404,000 *g* in a vertical rotor (Beckman VTi 65). The gradients were collected from the bottom in 40 fractions and were standardized with the following proteins: fluorescein isothiocyanate–labeled bovine serum albumin (molecular weight 67,000) and fluorescein isothiocyanate–labeled immunoglobulin G (molecular weight 150,000) (Behring Werke, Marburg, West Germany).

Purification of SHBG and CBG. Human SHBG or CBG was purified to homogeneity by application of three different chromatographic methods as previously described in detail.[18, 19]

Results

Serum proteins

Competition experiments. The determination of the relative binding affinities (RBA values) allows an evaluation of the specific interaction between a ligand and the binding site of steroid-binding serum proteins such as CBG and SHBG or of intracellular receptor proteins in relation to a radioactively labeled standard ligand typical of the respective binding protein. Table I and Fig. 1 summarize the results of the competition behavior of progesterone as compared with different established synthetic progestogens tested on specific serum proteins. In contrast to progesterone, which binds to CBG with an RBA value of 53% when compared with cortisol (100%), a natural affinity of all synthetic progestogens for CBG could not be established. With regard to binding to SHBG, gestodene, levonorgestrel—and to a lesser extent 3-ketodesogestrel—show a behavior that is typical of 19-nortestosterone derivatives and that is manifested in the relatively high affinity to SHBG when compared with DHT (100%). The RBA value for levonorgestrel is 50%, for gestodene 40%, and for 3-ketodesogestrel, 5%, whereas progesterone does not bind to SHBG. The synthetic progestogens from the C-21 series, medroxyprogesterone acetate and cyproterone acetate, along with the highly potent synthetic ligands for progesterone receptor analysis, Org2058 and R5020, are characterized by a lack of binding to both steroid-binding serum proteins. The same is also true for norgestimate.

Association and dissociation rates. Kinetic parameters such as association and dissociation rates of steroid hormone serum protein complexes provide important information as to the stability of such complexes.

The dissociation of different steroid hormones from the binding areas of serum proteins was measured by treatment of diluted serum of pregnant women or purified human SHBG and CBG with dextran-coated charcoal that had been incubated with the corresponding tritium labeled steroid under conditions of saturation. Fig. 2 and Table II document that levonorgestrel and gestodene dissociate much more slowly, both from the binding sites of pregnancy serum and from the binding sites of purified SHBG, than 3-ketodesogestrel and DHT (which was used as a reference steroid for the specific detection of SHBG). This is a manifestation of relatively stable steroid-protein complexes.

Table II. Dissociation rates of different steroid hormone serum protein complexes

Steroid	*Diluted serum of pregnant women*	*Purified SHBG*	*Purified CBG*
Progesterone	4.4	n.m.	4.8
DHT	6.6	5.1	n.m.
Levonorgestrel	29.3	11.8	n.m.
Gestodene	23.8	26.4	n.m.
3-Ketodesogestrel	3.8	2.6	n.m.

Values are half-life minutes.
n.m., Not measured.

Table III. Association rates (80% values) of different steroid hormones with specific binding components of diluted serum of pregnant women and purified SHBG

Steroid	*Diluted serum of pregnant women*	*Purified SHBG*
Progesterone	12	n.m.
DHT	12	90
Levonorgestrel	12	18
Gestodene	12	18
3-Ketodesogestrel	>>240	>>240

Values are association rates in minutes.
n.m., Not measured.

The kinetics of the association of different tritium-labeled steroid hormones with the specific binding sites of serum proteins over a period of 4 hours are shown in Table III and Fig. 3. After saturation of the binding sites from diluted serum of pregnant women or purified SHBG with tritium-labeled gestodene, levonorgestrel, and DHT within 12 minutes (80%) values, the specific binding remains stable over a period of at least 4 hours at 4° C. The association kinetics of 3-ketodesogestrel established in pregnancy serum or purified SHBG demonstrate that there was no saturation of the binding sites even after 4 hours of incubation under saturation conditions.

Scatchard plot analysis. The titrations of the specific binding sites with DHT, gestodene, levonorgestrel, and 3-ketodesogestrel in diluted human serum of pregnant

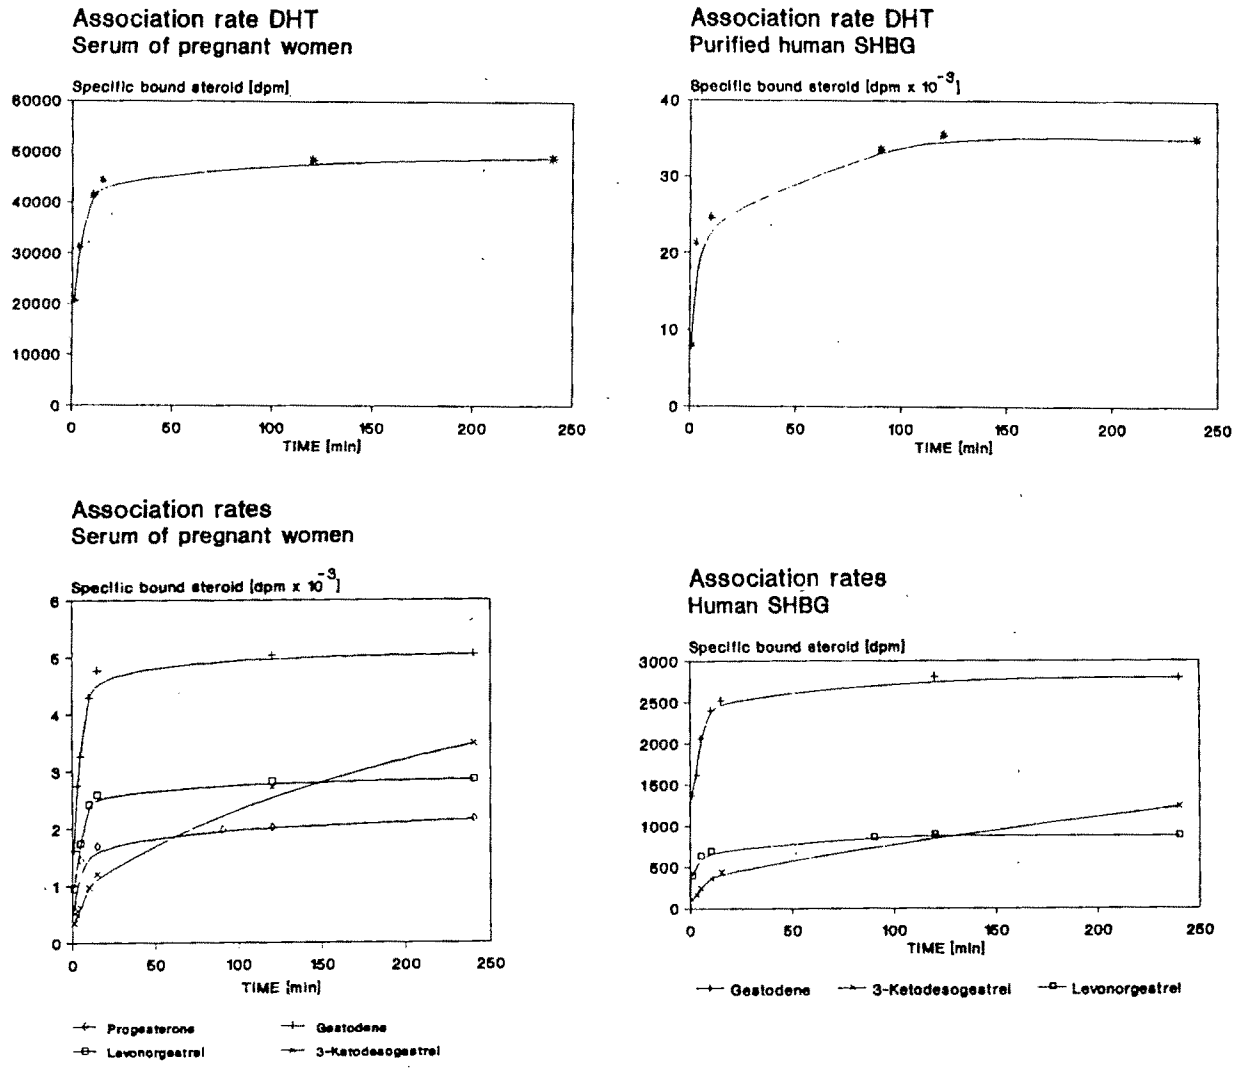

Fig. 3. Time course of association of various tritium-labeled steroids with diluted serum of pregnant women and purified human SHBG.

Table IV. Determination of K_d values according to Scatchard of different steroids in diluted serum of pregnant women

Steroid	*K_d values*
DHT	1.9×10^{-9} mol/L after 10-minute DCC treatment
Levonorgestrel	1.3×10^{-8} mol/L after 10-minute DCC treatment
Gestodene	1.0×10^{-8} mol/L after 10-minute DCC treatment
3-Ketodesogestrel	n.m. after 10-minute DCC treatment
3-Ketodesogestrel	1.9 ± 10^{-8} mol/L after 5-minute DCC treatment

n.m., Not measured.

women show that after transformation of the binding data according to Scatchard there is a typically linear correlation between bound/free and tritium-labeled ligand concentrations. The dissociation constants (K_d values), determined arithmetically from the Scatchard plot analysis, are $K_d = 1.9 \times 10^{-9}$ mol/L for DHT, whereas the K_d values for gestodene and levonorgestrel are one order of magnitude lower under conditions of 10 minutes of DCC treatment (Table IV). In contrast to this, a titration according to Scatchard is not possible owing to the extreme lability of the steroid-protein complex when 3-ketodesogestrel is used as a ligand under the condition of 10 minutes of DCC treatment for separation of free and protein-bound steroid. Only the reduction of the incubation time with DCC to 5 minutes allows an arithmetic determination of the binding data according to Scatchard ($K_d = 1.9 \times 10^{-8}$ mol/L) in this case.

Receptor studies

Competition experiments. Table V summarizes the results of competition experiments on the level of progesterone receptor from human uterine tissues with various reference steroids. R5020 is the reference

Table V. Relative binding affinities (%) of different progestogens for binding to human uterine progesterone receptor

Cyproterone acetate	6	8	6	<0.1
Medroxyprogesterone acetate	29	160	5	<0.1

steroid most frequently used in receptor studies. When employing R5020, it is shown that the progestogens such as cyproterone acetate, gestodene, and levonorgestrel (which are frequently used in oral contraceptives) and the biologically active metabolite 3-ketodesogestrel (which is only formed from the prodrug desogestrel in the body) bind to the progesterone receptor with high affinity apart from slight differences. The RBA values are markedly higher than those of progesterone, the natural gestagen. No measurable binding affinity at the progesterone receptor could be demonstrated for norgestimate in the system used, indicating that this substance (similar to desogestrel) constitutes a prodrug that must be transformed into the biologically active form by metabolic processes in the body.

If tritium-labeled gestodene, 3-ketodesogestrel, or levonorgestrel are used as reference steroids, a different arrangement is seen in the hierarchy of the RBA values in some cases (Table V and Fig. 4). For example, R5020 is only a weak competitor when compared with the reference steroids mentioned. Thus, 3-ketodesogestrel is able to displace gestodene from its binding sites in the uterine cytosol only with a reduced binding affinity, whereas gestodene conversely proves to be a high-affinity competitor for tritiated 3-ketodesogestrel.

Gestodene, 3-ketodesogestrel, and medroxyprogesterone acetate bind with relatively high affinity for the glucocorticoid receptor from rat livers of adrenalectomized animals comparable to that of progesterone, whereas cyproterone acetate, and to a greater extent levonorgestrel, only interact with lower affinity with the binding area of the glucocorticoid receptor (Table VI and Fig. 5).

The high affinity of gestodene when compared with that of the mineralocorticoid receptor from kidney cytosol of adrenalectomized rats is striking (Table VI and Fig. 5). In relation to aldosterone, the RBA value is 350%, which indicates a strong mineralocorticoid or antimineralocorticoid action of this compound at the receptor level. Medroxyprogesterone acetate, levonorgestrel, and progesterone, the natural gestagen itself, also have high binding affinities to the mineralocorticoid receptor, whereas 3-ketodesogestrel and norgestimate do not display any measurable affinity for this receptor species.

Furthermore, gestodene, levonorgestrel, and 3-ketodesogestrel bind with relatively high affinity to the

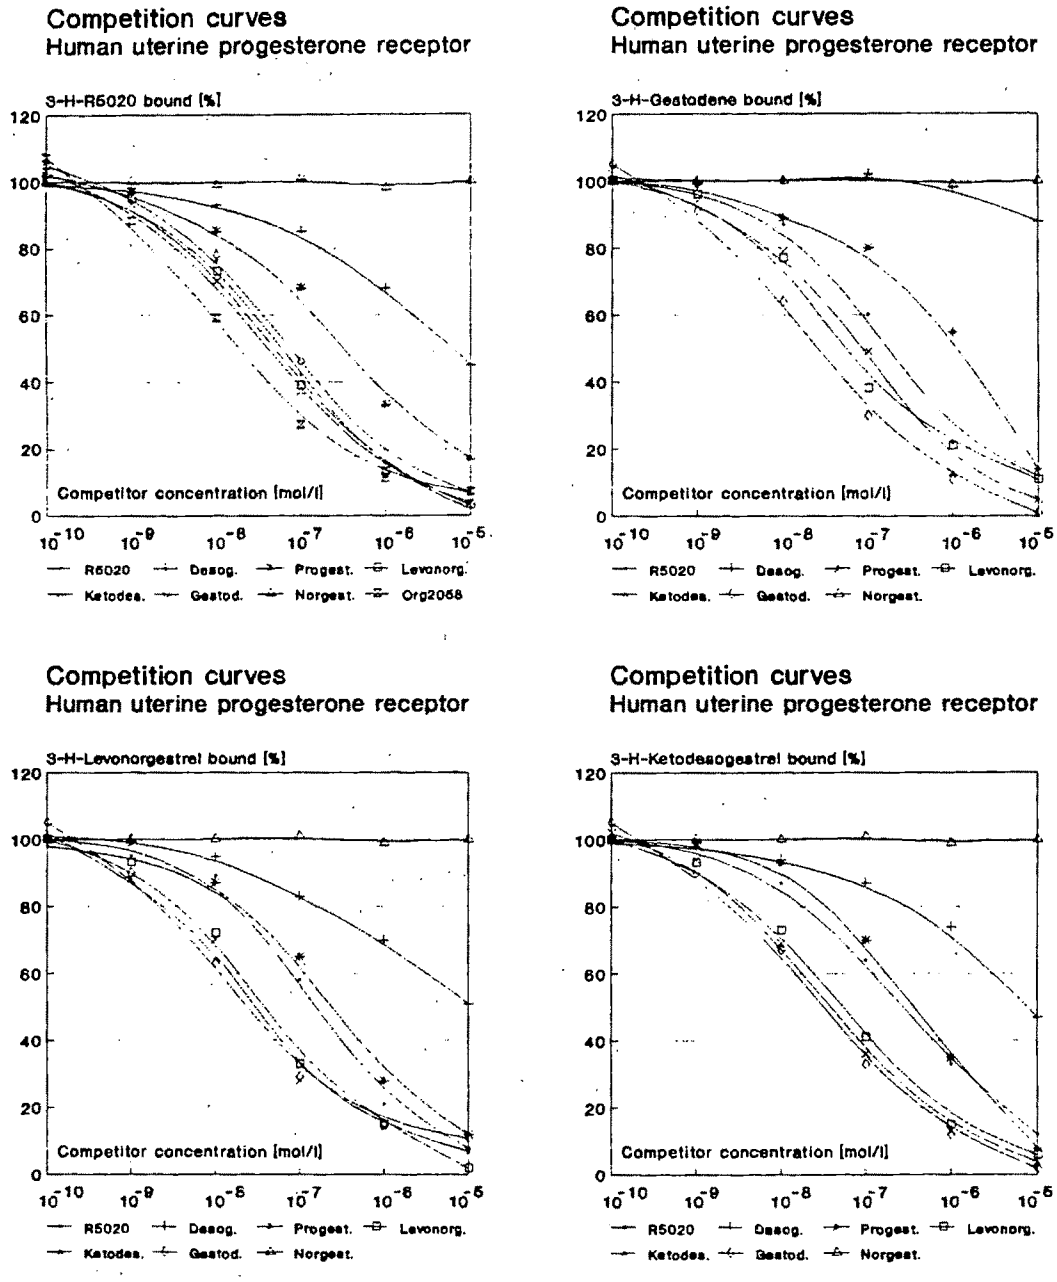

Fig. 4. Specificity of the binding of different tritium-labeled progestins to the cytoplasmic progesterone receptor in human uterus.

androgen receptor from prostate cytosol of rats but to a lesser extent (Table VI and Fig. 5). Cytoproterone acetate acts as a highly effective antiandrogen in addition to its partial gestagen effect. Astonishingly, it displays an RBA value of only 6% compared with the synthetic ligand R1881 (functioning as reference steroid [=100%]).

Estrogen receptor affinity could not be demonstrated in any of the progestogens investigated (Table VI and Fig. 5).

Sucrose density gradient centrifugation. Fig. 6 shows density gradient profiles of human uterine cytosol, which was incubated with different tritium-labeled synthetic progestogens. Tritium-labeled progesterone receptor complexes that settled as sediment in the 8S and 4S region of the linear sucrose gradient can be demonstrated for all ligands tested. In contrast to Org2058, a highly potent synthetic ligand for progesterone receptor analysis, it is evident that when gestodene, levonorgestrel, or 3-ketodesogestrel are used as ligands, a high proportion of tritium binding in the 4S region is to be observed. The ligand cannot be displaced, even with high molar excess of authentic steroid or Org2058.

This is to be rated as manifestation of relatively high

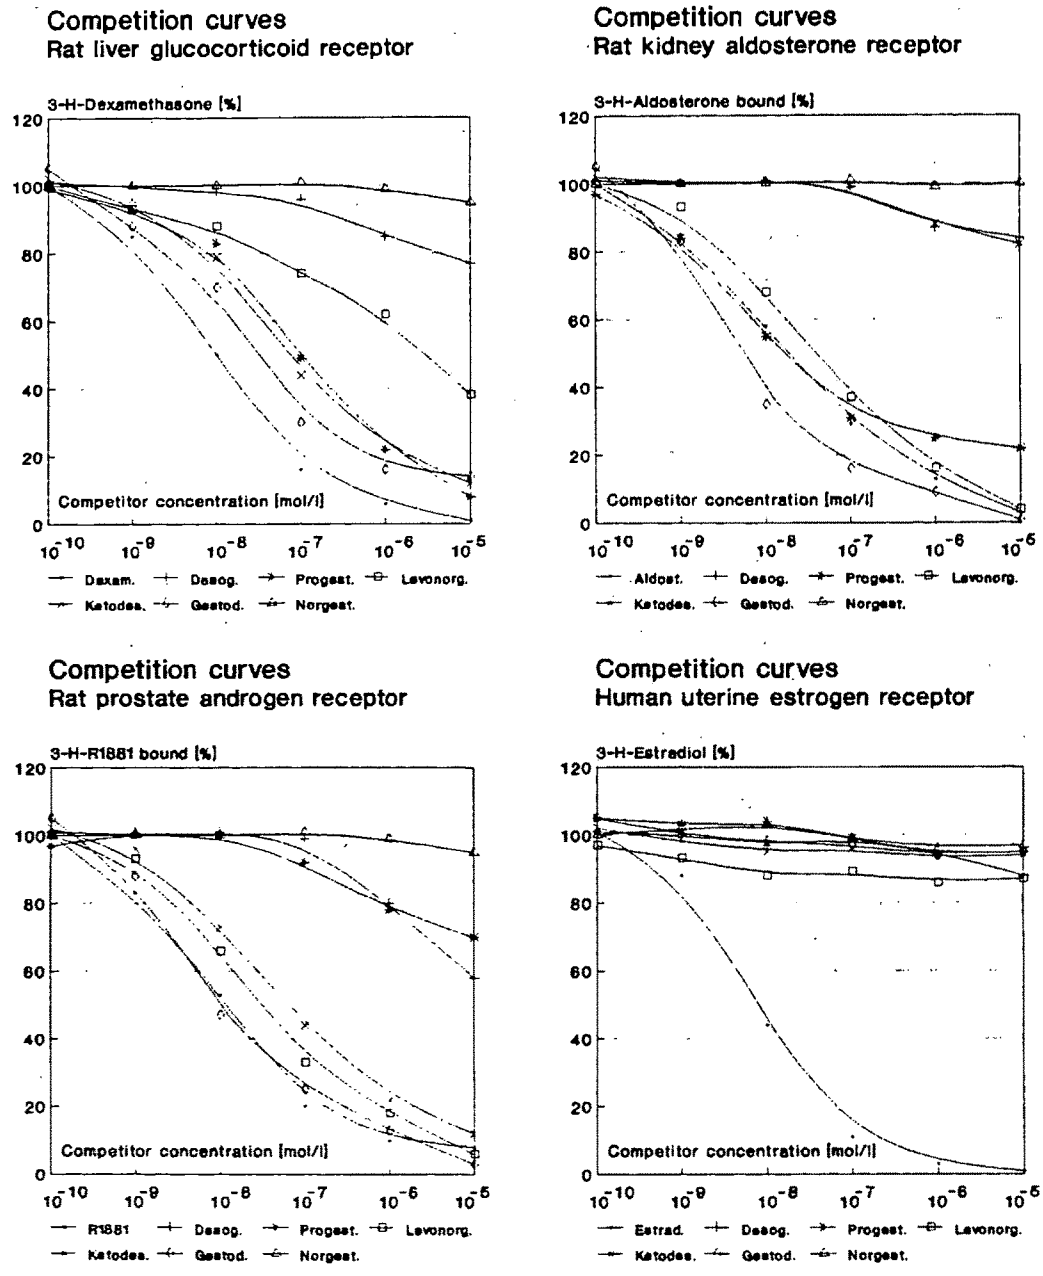

Fig. 5. Specificity of the binding of different tritium-labeled steroids to the cytoplasmic glucocorticoid receptor of rat liver, mineralocorticoid receptor of rat kidney, androgen receptor of rat prostate, and estrogen receptor of human uterus.

nonspecific binding activity of these synthetic ligands for uterine cytosol.

Comment

In terms of present day understanding, it is generally accepted that a correlation seems to exist between receptor binding of steroid hormones and biologic activity of these compounds in vivo. In this connection, however, it is to be mentioned that competitive analysis, with which the binding affinities are measured as compared with a reference steroid as RBA values, is doubtless incapable of establishing whether high binding affinity acts agonistically or antagonistically at the receptor level. In vivo experiments will be required to establish this characteristic.

In the Clauberg test, the standard method of determining gestagenic activity—because it detects the capacity of the progestogen to transform the estrogen-stimulated endometrium—gestodene is superior to all known progestogens including 3-ketodesogestrel.[12] For example, gestodene is three times more potent than levonorgestrel. However, this does not reflect the sit-

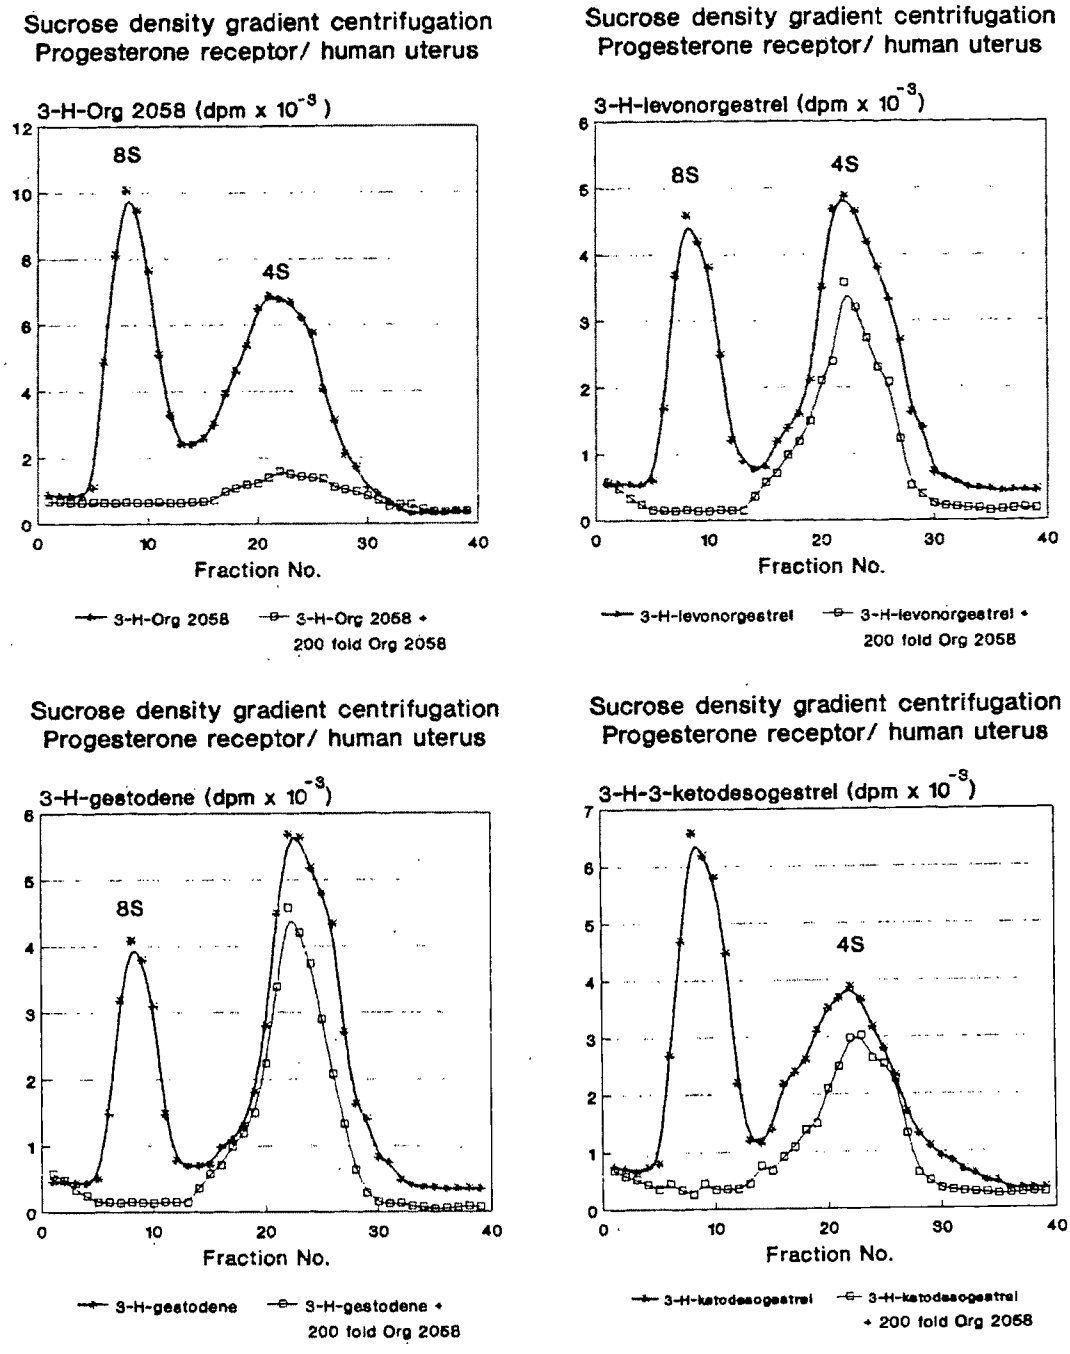

Fig. 6. Sucrose density gradient centrifugation of human myometrial cytosol preincubated with different tritium-labeled synthetic progestins.

uation with regard to the affinity to the progesterone receptor. In this connection it should be mentioned that in vitro binding affinities were determined at 4° C, whereas clinically relevant receptor binding occurs at 37° C.

An important aspect of the endocrinologic profile of progestogens of the gonane series is their androgenic activity. It is surprising to find that gestodene, despite its distinctly more powerful binding affinity to the androgen receptor, does not possess correspondingly more potent androgenicity than levonorgestrel or 3-ketodesogestrel (Herschberg test).[12]

Attention should be drawn to the fact that gestodene has a surprisingly high affinity for the aldosterone receptor. This affinity corresponds to weak antialdosterone activity in adrenalectomized rats,[12, 20] in which gestodene partially blocks the elimination of sodium with the urine. Whether this can have any clinical significance is doubtful, because significantly higher dosages of gestodene are needed for the antialdosterone activity

in comparison to the low level that exerts contraceptive efficacy in women. In this respect, gestodene can be compared with progesterone which, in physiologic doses, has a natriuretic effect in humans.[21-24] In contrast, 3-ketodesogestrel is characterized by a lack of binding to the mineralocorticoid receptor of kidney tissue of adrenalectomized rats. Furthermore, the competition studies demonstrated that desogestrel (but also norgestimate) function as prodrugs because the pattern of binding at the hormone receptors show no affinity.

As anticipated, sucrose gradient centrifugation analysis of cytosol of human myometrial tissue after saturation with tritium-labeled R5020, gestodene, cyproterone acetate, levonorgestrel, and 3-ketodesogestrel showed that the progestogen-binding components sedimented in the 4S and 8S region. In use of tritiated R5020 as binding partner, a 200-fold molar excess of nonradioactive R5020 almost led to complete reduction of the radioactivity, both in the 8S and in the 4S region. On the other hand, only a reduction of the 8S binding is to be observed in use of the other synthetic tritium-labeled progestogens in the presence of a 200-fold molar excess of nonradioactive authentic progestogen itself or R5020 as competitors. Binding of 4S was not reduced, which indicates the existence of a second high-capacity binding component. The nature of this binder is speculative. Because a 200-fold molar excess of nonradioactive DHT also does not lead to any appreciable reduction in protein-bound radioactivity in the 4S region, SHB is to be largely ruled out as binder.

The nonspecific binding in the 4S binding area visualized by sucrose density gradient analysis is reflected in the results obtained by HPLC analysis. Here, binding peaks are also to be observed that are not imaged in use of tritiated Org2058, or are only restricted to a limited extent in the presence of a 200-fold molar excess of nonradioactive Org2058 in the remaining spectrum of tritium-labeled progestogens.

As mentioned in the beginning, the biologic activity of a synthetic as well as a natural steroid hormone is not determined only by the binding properties on the receptor level; in addition, the distribution of steroid hormones between various protein-bound and nonprotein-bound components of the serum is of crucial importance for the bioavailability in different target tissues.

The binding of several contraceptive steroids to SHBG has been studied in detail,[25-32] and some information is available on the relative binding of ethinylestradiol, norethisterone, and levonorgestrel to serum albumin, but little information is available about how changes in circulating concentrations of steroid-binding proteins influence the plasma distribution of endogenous or contraceptive steroids.

In several publications,[31-33] it is reported that oral contraceptives that contain gestodene, but also 3-ketodesogestrel (much used progestogens in low-dose oral contraceptives of the most recent generation), lead to an increase of SHBG and CBG blood levels in consequence of increased hepatic synthesis of these proteins induced by high concentrations of ethinylestradiol in the hepatic-portal circulation. With regard to levonorgestrel, it is of interest to note that the same effect was not seen for SHBG. Levonorgestrel suppresses the ethinylestradiol-induced increase in serum SHBG as a function of the ratio of the levonorgestrel/ethinylestradiol doses in the pill, but its mechanism of action is not known. With regard to CBG, levonorgestrel (similar to gestodene and 3-ketodesogestrel) also leads to an increase of the serum concentration similar to that observed in women given ethinylestradiol alone.

Recently, in a comparison study with two low-dose oral contraceptives (one preparation contained 150 μg desogestrel and 30 μm ethinyl estradiol and the other preparation contained 75 μg gestodene as gestagenic component), Kuhl et al.[33-35] were able to show the following:

1. Serum levels of 3-ketodesogestrel, the biologically active metabolite of desogestrel, and gestodene rose in the course of an administration cycle.
2. Up to the third cycle of administration, the gestodene concentration revealed identical time courses in each cycle of administration. After 1 year, a fall in concentration was measured for 3-ketodesogestrel alone.
3. The absolute concentrations of gestodene and the rises within a cycle and over the first three cycles were higher than with 3-ketodesogestrel.
4. For gestodene, an unequivocal dependence of the serum levels on the concentration of SHBG was demonstrated. This was not the case for 3-ketodesogestrel.

One objective of the present study was to characterize the binding properties on the level of serum proteins of numerous synthetic progestins used in oral contraceptives. Summarizing the results, the following observations can be made: compared with levonorgestrel and gestodene, 3-ketodesogestrel reveals a relative binding activity with regard to SHBG that is one order of magnitude lower. This finding tends to corroborate the results of other authors.[25-33] Furthermore, marked differences in the binding kinetics between these synthetic progestogens are striking. Gestodene and levonorgestrel both form long-lived steroid protein complexes with SHBG, whereas the SHBG complexes formed with 3-ketodesogestrel are characterized by a short half-life.

If the results of Kuhl and associates,[33-35] with regard to higher gestodene blood levels with half the dosage when compared with 3-ketodesogestrel, are evaluated

in the light of this data, it can be observed that the results presented (in combination with the observation of the elevation of SHBG blood levels under oral contraceptives containing gestodene or desogestrel made by numerous authors[25, 33-35]) are sufficient to explain this phenomenon of the increase of gestodene over the administration cycles by higher affinity of binding to steroid-binding serum proteins as well as formation of stable gestodene-SHBG complexes. Any other explanation—for example, the delayed enzymatic inactivation of gestodene by the inhibitory effect of this steroid on the microsomal P_{450} enzyme system of the liver postulated for example by Kuhl—is speculative and must first be validated by unequivocal experimental data.

Pharmacokinetics and pharmacodynamics of oral contraceptive steroids: Factors influencing steroid metabolism

Claudia Jung-Hoffmann, MD, and Prof. Dr. Herbert Kuhl, PhD
Frankfurt am Main, Federal Republic of Germany

The time-dependent alterations in the serum concentrations of ethinyl estradiol, gestodene, and 3-keto-desogestrel during treatment with 30 μg of ethinyl estradiol + 75 μg of gestodene or 30 μg of ethinyl estradiol + 150 μg of desogestrel were investigated during 12 months. The levels of gestodene and 3-keto-desogestrel increased between days 1 and 21 of each cycle, reaching maximal levels during the third and sixth cycles. The serum concentrations of gestodene were fourfold to fivefold higher than those of 3-keto-desogestrel. The ethinyl estradiol levels increased significantly between days 1 and 10 during each cycle and were significantly higher by 70% during intake of ethinyl estradiol/gestodene compared with ethinyl estradiol/desogestrel, although the dose was identical. Intake of gestodene, in addition to 35 μg of ethinyl estradiol + 2 mg of cyproterone acetate, caused a rise in ethinyl estradiol levels. During treatment with ethinyl estradiol/gestodene and an additional 150 μg of levonorgestrel, there was a continuous increase in gestodene levels, although sex hormone–binding globulin level did not change. During treatment with 30 or 35 μg of ethinyl estradiol and 75 μg of gestodene, 150 μg of desogestrel, or 2 mg of cyproterone acetate, there were large intraindividual and interindividual variations in the steroid levels and ratios of estrogen:progestogen levels. There was no correlation with the occurrence of intermenstrual bleedings. It is concluded that ethinyl estradiol and nortestosterone derivatives may inhibit steroid-metabolizing enzymes in the liver, which results in a rise in the serum levels of contraceptive steroids. The cause of the large intraindividual variations is as yet unknown, but it is probably from changes in steroid metabolism. (Am J Obstet Gynecol 1990;163:2183-97.)

Key words: Pharmacokinetics of contraceptive steroids, ethinyl estradiol, gestodene, 3-keto-desogestrel

Drug monitoring is considered as an approach to minimize adverse reactions and side effects by individual adjustment of the dose. Although the susceptibility of women to a given serum level may vary, the average biologic effects are assumed to be related to the serum concentration rather than to the dose ingested.

Because the pill must suppress ovulation reliably in all women, it is overdosed in many women. Even though contraceptive steroids have a large therapeutic margin, they may cause severe adverse effects. There are reports on elevated serum concentrations of ethinyl estradiol in women who developed hypertension during treatment with the pill.[1,2] Little information is available on correlations between contraceptive steroid levels and metabolic parameters. A significant inverse correlation has been observed between the serum levels of medroxyprogesterone acetate and high-density lipoprotein cholesterol.[3] No relationship was found between the serum levels of ethinyl estradiol or norgestrel and plasma Xa inhibitory activities.[4] Because of the large interindividual and intraindividual variations of the steroid concentrations, even after intravenous and vaginal application,[5-7] it will be difficult to recognize such correlations when only single blood samples were taken. Moreover, many of the metabolic parameters are

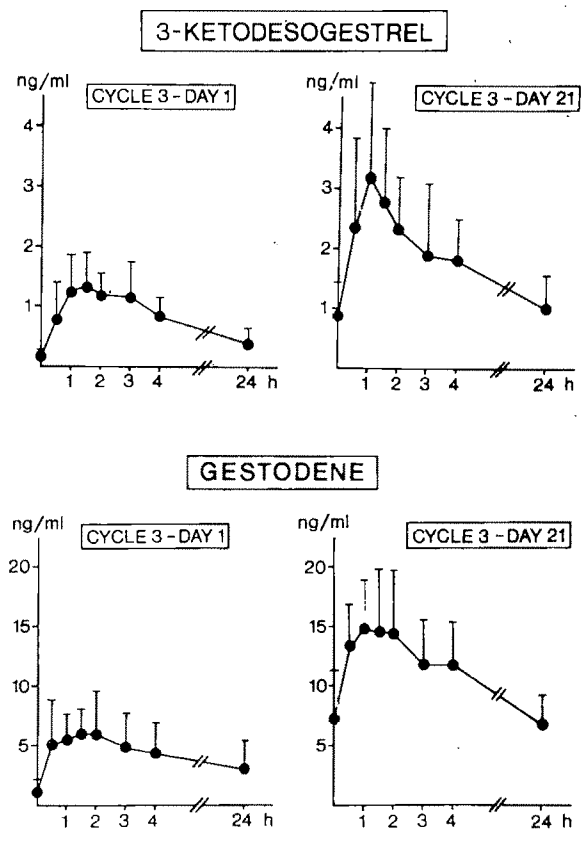

Fig. 1. Serum levels of 3-keto-desogestrel and gestodene on days 1 and 21 of the third cycle of treatment with 30 μg of ethinyl estradiol + 150 μg desogestrel or 30 μg of ethinyl estradiol + 75 μg of gestodene.

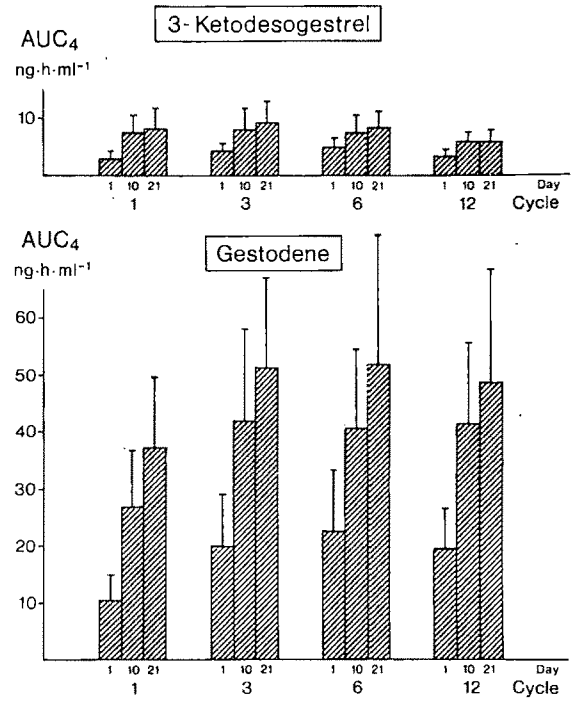

Fig. 2. Areas under the time versus serum concentration curves between 0 and 4 hours of 3-ketodesogestrel and gestodene during treatment with 30 μg of ethinyl estradiol + 150 μg of desogestrel or 30 μg of ethinyl estradiol + 75 μg of gestodene.

influenced by the estrogenic and progestogenic components in an antagonistic manner and may change with time of treatment. The alterations in hepatic metabolism during and after treatment with oral contraceptives take place with a lag time of several days or weeks. Therefore metabolic serum parameters may reflect an integral effect of average steroid levels rather than day-to-day variations. The measurement of steroid levels in single blood samples and even the determination of the concentration versus time curves on a single day represent more or less a snapshot that may differ from the long-term status of an individual woman.

In the present studies the individual serum concentrations of ethinyl estradiol and different progestogens during treatment with low-dose oral contraceptives were measured during the first 4 hours after intake of the pill and 24 hours after that on several days.

Material and methods

Study 1. Twenty-two normal healthy volunteers with regular menstrual cycles, between 18 and 35 years old, participated in the study. Informed consent was obtained. The women had not used hormonal contraceptives for at least 3 months before the study and were not under pharmacologic therapy. An internal and gynecologic examination, including a Papanicolaou smear, was carried out before the selection of the subjects. During a control cycle, ovulation was confirmed to have probably taken place by the determination of serum progesterone (>3 ng/ml).

Two groups of 11 women each were randomly assigned to take a combination of 30 μg of ethinyl estradiol and 75 μg of gestodene (Femovan, Schering AG, Berlin) or a combination of 30 μg of ethinyl estradiol and 150 μg of desogestrel (Marvelon, Organon GmbH, Oberschleissheim) during a 12-month period. Blood samples during fasting were obtained between 8:00 and 10:00 AM on days 1, 10, and 21 of the first, third, sixth, and twelfth treatment cycles immediately before and 0.5, 1, 1.5, 2, 3, 4, and 24 hours after ingestion of a tablet. After centrifugation, the serum was stored at −20° C until analysis.

Study 2. Twelve normal healthy volunteers with regular menstrual cycles, between the ages of 25 and 43 years, participated in the study. Informed consent was obtained. Except for volunteer No. 9 who took 150 μg of thyroxine daily, the women were not under pharmacologic therapy. An internal and gynecologic examination was carried out before the start of the study. The women were treated with a combination of 35 μg of ethinyl estradiol and 2 mg of cyproterone acetate (Diane 35, Schering AG, Berlin).

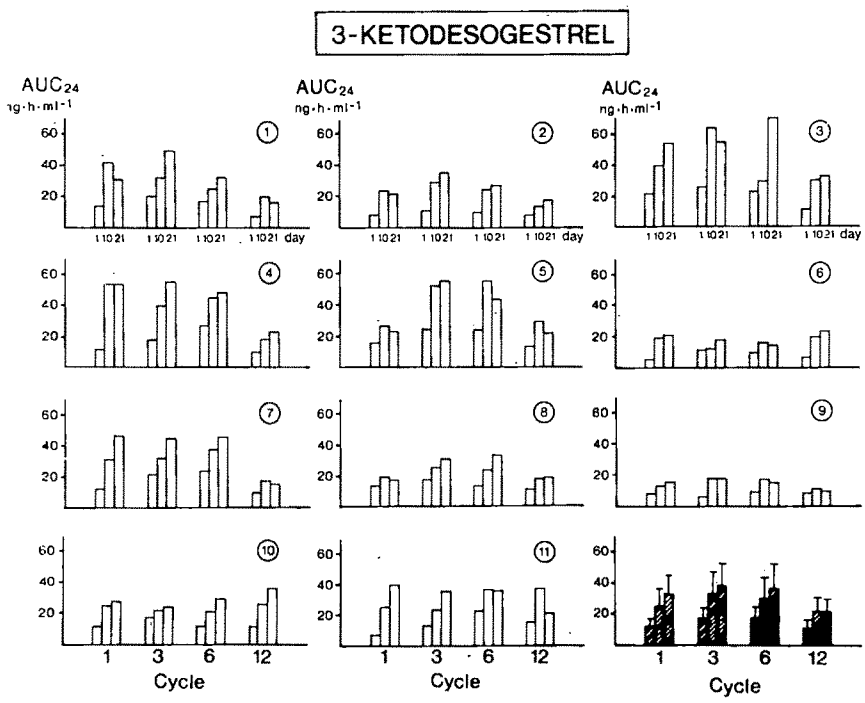

Fig. 3. Individual areas under the time versus serum concentration curves of 3-keto-desogestrel in 11 volunteers during 12 months of treatment with 30 μg of ethinyl estradiol + 150 μg of desogestrel *(hatched columns:* Mean ± SD).

Blood samples during fasting were taken between 8:00 and 10:00 AM on days 1, 10, and 21 of one cycle immediately before and 0.5, 1, 1.5, 2, 3, 4, and 24 hours after ingestion of a tablet. After centrifugation, the serum was stored at −20° C until analysis.

Study 3. One woman (one of the authors) ingested a combination of 35 μg of ethinyl estradiol and 2 mg of cyproterone acetate for 26 days. In addition, she took 150 μg of gestodene on days 6, 13, and 20, and 75 μg of gestodene on days 7, 8, 14, 15, 21, and 22. Blood samples during fasting were obtained between 8:00 and 10:00 AM on days 1, 5, 8, 12, 15, 19, 22, and 26 immediately before and 0.5, 1, 1.5, 2, 3, 4, and 24 hours after intake of the tablets. After centrifugation, the serum was stored at −20° C until analysis.

Study 4. The same woman switched from treatment with a combination of 35 μg of ethinyl estradiol and 2 mg of cyproterone acetate after a pill-free week to a combination of 30 μg of ethinyl estradiol and 75 μg of gestodene for one cycle, taking an additional 150 μg of levonorgestrel daily. After a hormone-free interval of 7 days, she took 30 μg of ethinyl estradiol and 75 μg of gestodene for one cycle. Thereafter, she ingested 150 μg of levonorgestrel daily during the interval of 7 days, and after that she started one cycle of treatment with 30 μg of ethinyl estradiol and 75 μg of gestodene and an additional 150 μg of levonorgestrel. Blood samples during fasting were taken between 8:00 and 10:00 AM on days 1, 10, and 21 of the cycle immediately before and 0.5, 1, 1.5, 2, 3, 4, and 24 hours after intake of a tablet. After centrifugation, the serum was stored at −20° C until analysis.

Laboratory methods. The serum concentrations of ethinyl estradiol were measured in duplicate by means of radioimmunoassay after extraction of 1 ml of serum with diethylether. The method has been described elsewhere in detail.[8] The serum concentrations of 3-keto-desogestrel, which is the biologically active metabolite of desogestrel, were determined in duplicate by means of radioimmunoassay after chromatographic fractionation. The method has been described elsewhere in detail.[9] The serum concentrations of gestodene were measured in duplicate by means of radioimmunoassay after extraction of 0.1 ml of serum with diethylether. The method has been described elsewhere in detail.[10]

Serum concentrations of sex hormone–binding globulin (SHBG) were determined by means of a "liquid phase" immunoradiometric assay kit (Farmos Diagnostica, Oulunsalo, Finland).

Statistical analysis. The areas under the serum concentration versus time curves between 0 and 24 hours were calculated by the trapezoidal rule. Data were statistically analyzed by multivariate analysis of variance (repeated measurements design) or by the Student paired *t* test.

Results

During each cycle of treatment with ethinyl estradiol/desogestrel or ethinyl estradiol/gestodene, the

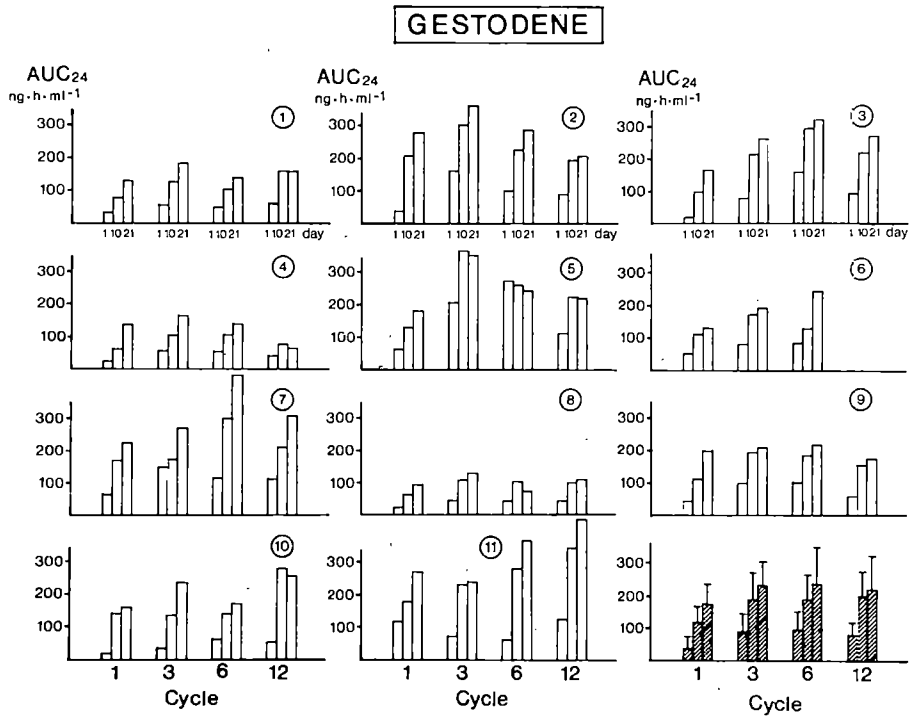

Fig. 4. Individual areas under the time versus serum concentration curves of gestodene in 11 volunteers during 12 months of treatment with 30 μg of ethinyl estradiol + 75 μg of gestodene (*hatched columns:* Mean ± SD).

serum concentrations of 3-keto-desogestrel and gestodene increased significantly from day 1, reaching maximal levels between days 10 and 21. During the third and sixth cycles, progestogen levels were significantly higher than during the first cycle (Fig. 1). Thereafter no further increase was observed. The 3-keto-desogestrel levels during the twelfth cycle were even significantly lower than before.[9, 10] When the areas under the curves (AUCs) between 0 and 4 hours (Fig. 2), as well as between 0 and 24 hours were compared, it was conspicuous that the levels of gestodene were fourfold to fivefold those of 3-keto-desogestrel, although the dose of gestodene was only half of that of desogestrel.[9, 10]

There were large intraindividual and interindividual variations both in the 3-keto-desogestrel and gestodene levels as demonstrated in the AUCs between 0 and 24 hours measured on days 1, 10, and 21 of the first, third, sixth, and twelfth cycles in all volunteers taking ethinyl estradiol/desogestrel (Fig. 3) or ethinyl estradiol/gestodene (Fig. 4). The average intraindividual and interindividual coefficients of variation were in the range between 30% and 70%, but were less pronounced in most women when the increases in steroid levels during each cycle were regarded as a rule. Some women showed permanently low 3-keto-desogestrel or gestodene levels, whereas others remained at relatively high progestogen concentrations throughout the 12 treatment cycles (Figs. 3 and 4).

When the serum concentrations of ethinyl estradiol were determined, the results were quite surprising. Although the ethinyl estradiol dose of 30 μg was identical in both preparations, ethinyl estradiol levels were significantly higher during intake of the gestodene-containing pill (Figs. 5 and 6). The calculation of the AUCs between 0 and 4 hours revealed a difference of 37% and between 0 and 24 hours 70% on average.[8] There was a close correlation between the AUCs 0 to 4 hours and the AUCs 0 to 24 hours. It is also remarkable that after intake of ethinyl estradiol/gestodene, the ethinyl estradiol peaks occurred 30 minutes to 1 hour later than with ethinyl estradiol/desogestrel. During each cycle of treatment with both preparations, there was a significant rise in ethinyl estradiol levels between days 1 and 10 that remained thereafter at this level, indicating that a steady state was reached between days 1 and 10 (Figs. 7 and 8; *hatched columns*). In contrast to the progestogen concentrations, there was no difference between the ethinyl estradiol levels of the first and those of subsequent cycles. Similar to the progestogen levels, there were large intraindividual and interindividual variations in the ethinyl estradiol concentrations. In some women, however, we found low estrogen levels on each of the 12 days investigated,

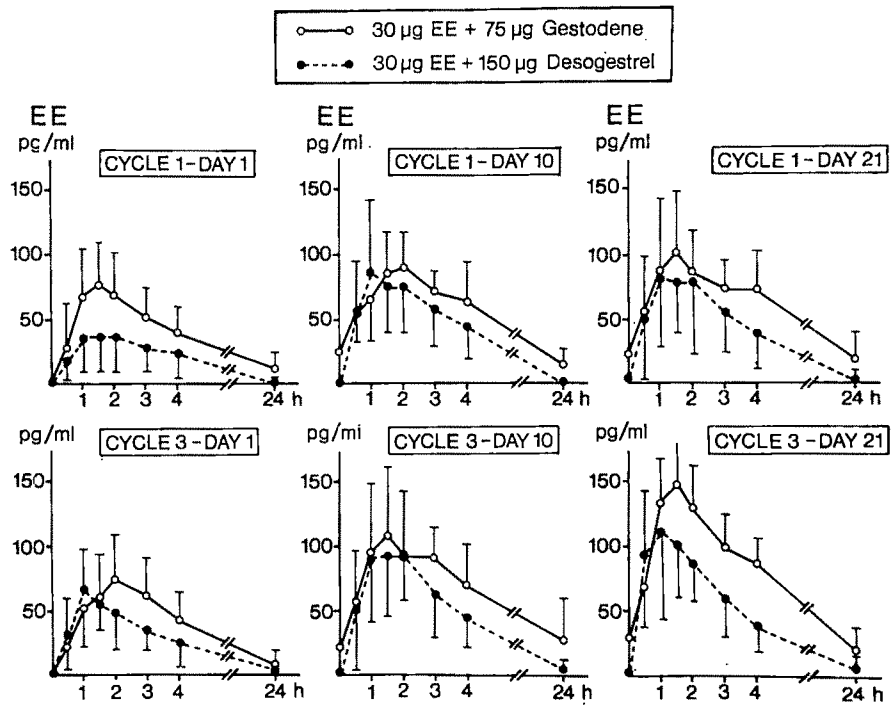

Fig. 5. Serum concentrations of ethinyl estradiol *(EE)* during 24 hours after intake of a tablet of ethinyl estradiol/gestodene or ethinyl estradiol/desogestrel on days 1, 10, and 21 of the first and third treatment cycles (mean ± SD). Fig. 6. Serum concentrations of ethinyl estradiol during 24 hours after intake of a tablet of ethinyl estradiol/gestodene or ethinyl estradiol/desogestrel on days 1, 10, and 21 of the sixth and twelfth treatment cycles (mean ± SD). (Reprinted from Jung-Hoffmann C, Kuhl H. Contraception 1989; 40:299-312, by permission of Butterworth-Heinemann [U.S.].)

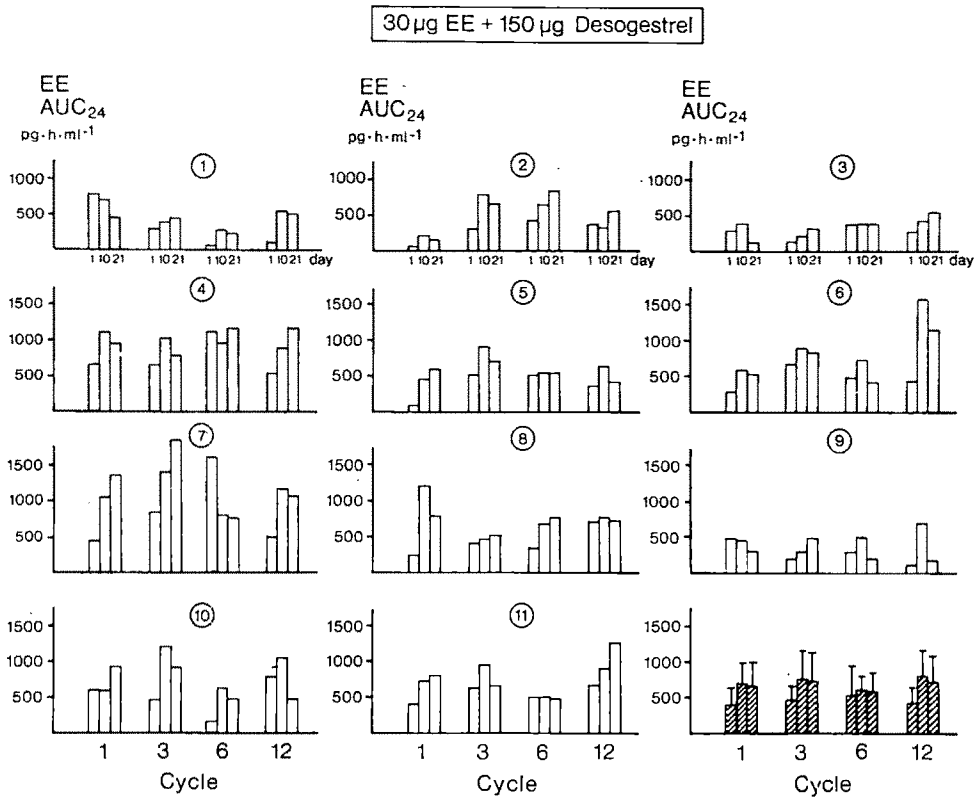

Fig. 7. Individual areas under the time versus serum concentration curves of ethinyl estradiol in 11 volunteers during 12 months of treatment with 30 µg of ethinyl estradiol + 150 µg of desogestrel (*hatched columns:* Mean ± SD).

whereas some other volunteers showed permanently high concentrations. When the individual ratios between the serum concentrations of ethinyl estradiol and 3-keto-desogestrel or gestodene were calculated, large intraindividual and interindividual variations were found (Figs. 9 and 10). As represented by the hatched columns, the average values show that in each cycle there was a gradual decrease in the estrogen/progestogen ratio between the first and last day of treatment.

Because large intraindividual variations may render it difficult to find a relationship between the serum levels of contraceptive steroids and intermenstrual bleedings or metabolic serum parameters, the average AUCs of ethinyl estradiol, the progestogens, and the ratios between both were calculated for each individual volunteer on the basis of the 12 days of measurement (Figs. 11 and 12). In both treatment groups there were considerable differences in the average values between the 22 volunteers. As demonstrated by the variances in the ratio between ethinyl estradiol and the progestogens, high or low estrogen levels were not always accompanied by corresponding high or low progestogen concentrations. There was also no correlation between body weight and the AUCs of the contraceptive steroids or the ratios.

When the pharmacokinetics of ethinyl estradiol were investigated during one cycle of treatment with 35 µg of ethinyl estradiol and 2 mg of cyproterone acetate, very large interindividual variations were also found.

One woman had extremely low ethinyl estradiol levels and another woman had very high estrogen concentrations (Fig. 13). There was a significant ($p < 0.01$) increase in estrogen levels between days 1 and 10 (Fig. 14) similar to treatment with ethinyl estradiol/desogestrel and ethinyl estradiol/gestodene.

The results of the single woman who took a combination of 35 µg of ethinyl estradiol and 2 mg of cyproterone acetate and additional gestodene on various days are shown in Fig. 15. There was a pronounced increase in the serum levels of ethinyl estradiol between days 1 and 5 when a steady state appeared to be reached with the preparation alone. The additional intake of gestodene resulted in a further rise in estrogen levels, whereas on those days without gestodene, the ethinyl estradiol concentrations were lower. To investigate the role of rising SHBG levels in the elevation of the serum concentration of gestodene between days 1 and 21 of

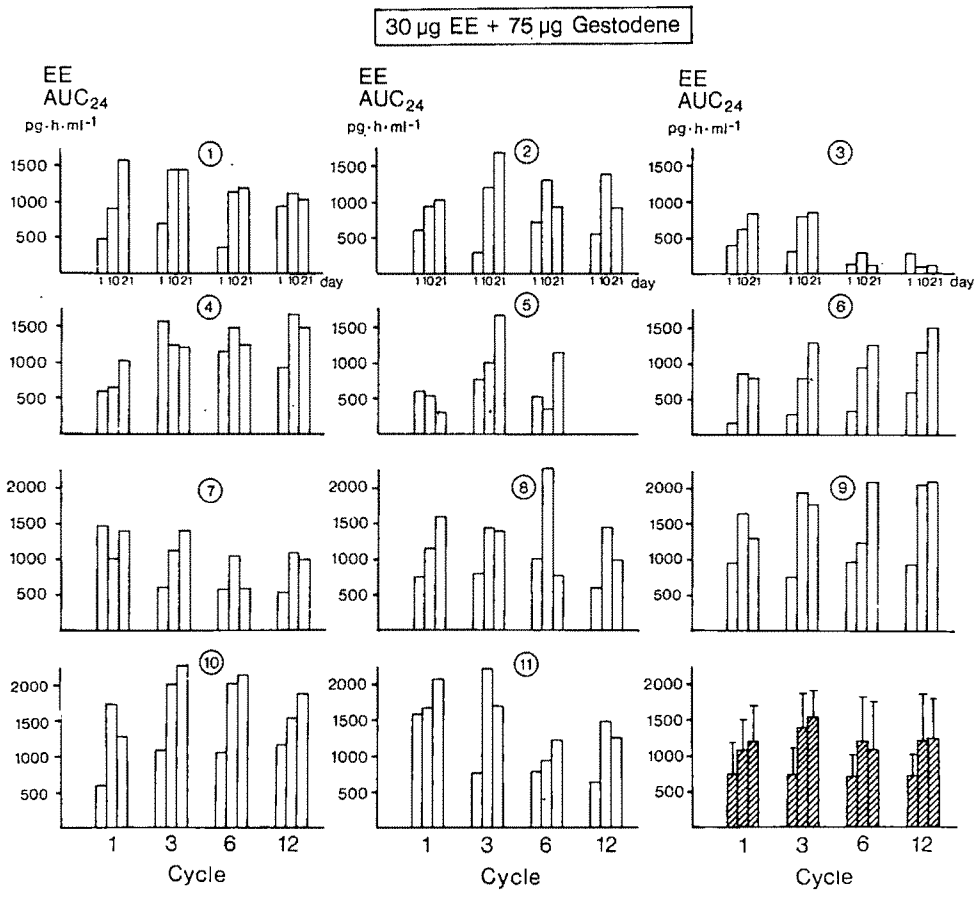

Fig. 8. Individual areas under the time versus serum concentration curves of ethinyl estradiol in 11 volunteers during 12 months of treatment with 30 µg of ethinyl estradiol + 75 µg of gestodene (*hatched columns:* Mean ± SD).

treatment with ethinyl estradiol/gestodene, additional levonorgestrel was taken, which is known to reduce SHBG serum levels because of its androgenic effectiveness. Based on the preceding intake of 35 µg of ethinyl estradiol and 2 mg of cyproterone acetate, SHBG levels were high even after the pill-free interval of 7 days. During treatment with 30 µg of ethinyl estradiol and 75 µg of gestodene and 150 µg of levonorgestrel daily, the initially high SHBG levels decreased by 50% until day 21 (Fig. 16). Nevertheless, gestodene concentrations increased by 35%. When ethinyl estradiol/gestodene was taken alone during the following cycle, the SHBG level increased by 50% between days 1 and 21, whereas the gestodene level rose by more than 300%. During the next pill-free interval of 7 days, she ingested 150 µg of levonorgestrel daily to reduce SHBG level. When she started to again take ethinyl estradiol/gestodene plus 150 µg of levonorgestrel, the gestodene concentrations increased by 100%, whereas SHBG levels rose only slightly until the end of the cycle.

Comment

The present study is the first that investigated in detail the pharmacokinetics of oral contraceptive steroids during a longer time period. The results confirm previous findings of large intraindividual and interindividual variations in the serum levels of ethinyl estradiol and the progestogens. Moreover, there was not only a continuous increase in 3-keto-desogestrel and gestodene levels during multiple intake, which reached a steady state between days 10 and 21, but also a significant rise in ethinyl estradiol concentrations between days 1 and 10. Although maximal progestogen concentrations were reached during the third and sixth cycles,[9, 10] there was no difference in estrogen levels between the first and subsequent treatment cycles.[8] Although the estrogen dose was identical, the observation of significantly higher ethinyl estradiol concentrations during intake of the gestodene-containing pill compared with the combination of ethinyl estradiol with desogestrel indicates an influence of the progestogen

component on the pharmacokinetics of ethinyl estradiol. To date interactions between sex steroids have been known only in regard to the stimulation of serum protein-binding capacity by ethinyl estradiol of nortestosterone derivatives.

Pharmacokinetics of progestogens. The striking difference in the height of the serum concentrations of gestodene and 3-keto-desogestrel was suggested to be exclusively the consequence of the strong binding affinity of gestodene to SHBG, whereas that of 3-keto-desogestrel is much less.[1] Actually, the correlation between SHBG and gestodene was close and that between SHBG and 3-keto-desogestrel was less close.[9, 10] However, correlation does not mean causal relationship. The relative binding affinities to SHBG compared with levonorgestrel were 80% for gestodene and 10% for 3-keto-desogestrel,[11] whereas Bergink et al.[12] found 32% of the binding affinity of levonorgestrel for 3-keto-desogestrel. However, the physiologic significance of binding experiments with dialysis is questionable; it had been demonstrated that, for instance, a low dialyzable percentage of 6% for estradiol does not correlate with the high influx of estradiol into the liver (90%), brain (72%), and uterus (38%) during perfusion experiments.[13] Binding to albumin has nearly no influence on the biologic effectiveness as exemplified with testosterone.[14] The short half-life of testosterone despite its high binding affinity to SHBG, which is threefold that of levonorgestrel, indicates that hepatic metabolism is in all probability the main determinant of the bioavailability of synthetic sex steroids. If the metabolic capacity of hepatic cytochrome P-450–dependent enzymes is the rate-limiting factor, the concentration of free steroid in plasma will be the same as within the hepatocytes,[15] and a slow-down of hepatic inactivation will result in an accumulation of the total steroid level in plasma. A rise in total gestodene concentration implies a corresponding increase in free gestodene levels. The calculation of biologically effective gestodene and 3-keto-desogestrel plasma levels on the basis of the AUCs of the present study and the percentage of non-SHBG-bound gestodene (24%) and 3-keto-desogestrel (68%)[16] revealed that, for example, on day 21 of the third cycle, the non-SHBG-bound amount of gestodene is more

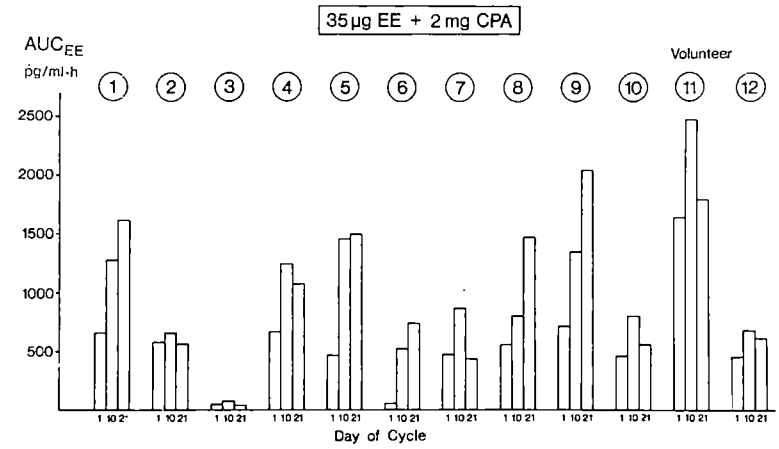

Fig. 13. Individual areas under the time versus serum concentration curves of ethinyl estradiol in 12 volunteers on days 1, 10, and 21 of one cycle of treatment with 35 µg of ethinyl estradiol + 2 mg of cyproterone acetate (CPA).

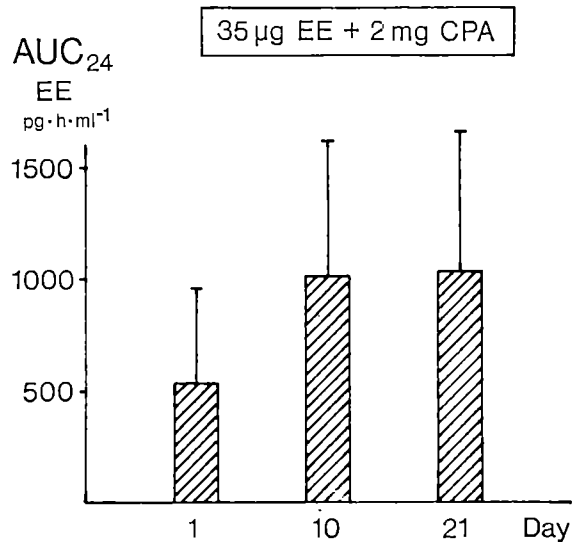

Fig. 14. Areas under the time versus serum concentration curves between 0 and 24 hours of ethinyl estradiol during treatment of 12 women with 35 µg of ethinyl estradiol + 2 mg of cyproterone acetate *(CPA)* for one cycle (mean ± SD).

than twice that of 3-keto-desogestrel (56.6 vs 26.0 ng · hr/ml). With regard to the role of binding of sex steroids to SHBG as a neutralizing factor of biologic effectiveness, recent data throw some doubt on this hypothesis and show that binding to SHBG might be important for an active process of uptake of steroids by target organs.[17, 18]

There are as yet no data on the inactivation rate of the modern progestogens by hepatic enzymes. The significant correlation between the serum concentrations of SHBG and levonorgestrel indicates a pronounced influence of protein binding on metabolic clearance of levonorgestrel.[19-21] On the other hand, two women had no or a negative correlation between SHBG and levonorgestrel levels.[20] In another study there was a continuous increase in levonorgestrel plasma levels throughout a cycle of treatment with 30 µg of ethinyl estradiol and 150 µg of levonorgestrel, although SHBG levels remained unchanged.[22] The authors stated that the rise in levonorgestrel levels cannot be explained by increased binding to SHBG, but it is more likely because of changes in levonorgestrel metabolism. The present results of the time course of SHBG and gestodene during intake of the gestodene-containing pill with or without additional levonorgestrel indicate a strong influence of SHBG binding on gestodene levels, but also the effect of another factor, which is possibly the inhibition of gestodene metabolism.

In a recent study Brody et al.[23] reported on significantly higher norethisterone levels during intake of 50 µg of mestranol and 1 mg of norethisterone compared with 35 µg of ethinyl estradiol and 1 mg of norethisterone, whereas the levels of ethinyl estradiol did not differ. The authors discussed a possible effect of the different estrogens on norethisterone metabolism. It is remarkable that the demethylation of mestranol, which leads to ethinyl estradiol, is catalyzed by cytochrome P-450–dependent enzymes, which also metabolize various steroids and drugs.

Pharmacokinetics of ethinyl estradiol. The significant increase in the levels of ethinyl estradiol, reaching a steady state between days 1 and 10, which can be observed during treatment with different preparations, cannot be the result of a rise in protein binding in serum. Ethinyl estradiol is nearly exclusively bound by albumin, the concentration of which is not influenced by oral contraceptives. It is not probable that an accumulation of ethinyl estradiol sulfate in the blood, which resulted in an elevated enterohepatic recirculation, may be involved, because the sulfates of ethinyl estradiol have been demonstrated not to be slow-release

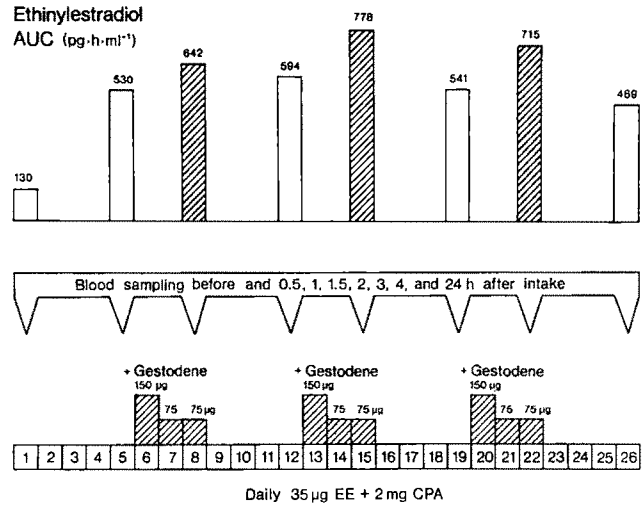

Fig. 15. Areas under the time versus serum concentration curves between 0 and 24 hours of ethinyl estradiol in one woman during treatment with 35 µg of ethinyl estradiol + 2 mg of cyproterone acetate *(CPA)* for 26 days with or without additional gestodene.

reservoirs.[24] The increase in the ethinyl estradiol level and the parallel prolongation of the half-lives of ethinyl estradiol and theophyllin during long-term treatment with an oral contraceptive indicate an inhibition of hepatic metabolism of the steroid and the drug, both of which are inactivated by cytochrome P-450–dependent enzymes.[25] There is a series of drugs, the half-lives of which are increased, and metabolic clearance is decreased during treatment with oral contraceptives.[26] The results of Guengerich[27] indicate that ethinyl estradiol and some progestogens containing an ethinyl group are capable of inhibiting the 2-hydroxylation of ethinyl estradiol. An increase in ethinyl estradiol levels during a cycle of treatment with preparations containing 30 or 50 µg of ethinyl estradiol has also been observed.[28] During multiple intake of daily 30 or 50 µg without progestogens, there was a continuous increase in ethinyl estradiol concentration, which reached a steady state after 7 days with the higher dose and after 12 or more days with 30 µg.[29]

It is improbable that the difference in ethinyl estradiol levels during intake of ethinyl estradiol/desogestrel and ethinyl estradiol/gestodene is because of galenic diversities. The pharmacokinetic parameters of identically composed oral contraceptives of different producers were identical.[23, 30, 31] The higher ethinyl estradiol levels during treatment with the gestodene-containing pill can be explained with an inhibitory influence of gestodene that is circulating in very high concentrations on 2-hydroxylation of ethinyl estradiol. This progestogen has been shown by Guengerich[27] to be an extreme inhibitor of this metabolic reaction in human liver microsomes. It should be kept in mind that during the first liver passage, the serum concentrations of steroids after oral intake are several times higher than those measured peripherally.[32] Therefore during the first passage through the liver, local gestodene concentrations of >100 ng/ml might be reached in the sinusoids, a part of which may penetrate into the hepatocytes and interact with metabolic enzymes. Concerning the physiologic significance of these steroid concentrations, which are much lower than those used in vitro,[27] it is interesting that the endocrine and clinical effects of a new potent aromatase inhibitor, 4-hydroxy-androstenedione, are maintained with relatively low serum levels of 7.8 ± 1.1 ng/ml after intramuscular injection of a microcrystalline suspension.[33] The 4-hydroxy-androstenedione acts as a suicide inhibitor, destroying the cytochrome P-450–dependent aromatase irreversibly.[31]

The supposition can be made that both ethinyl estradiol and nortestosterone derivatives contribute to the inhibition of their metabolism, as well as that of those drugs that are metabolized by cytochrome P-450–dependent enzymes. Regarding the effectiveness of progestogens alone, a decrease in the metabolic clearance rate of aminopyrine by 25% to 35% has been reported in women treated with 0.35 mg of norethisterone daily.[35] The mechanism of the interaction of steroids with cytochrome P-450 enzymes is only partly known. The principal metabolite of ethinyl estradiol, 2-hydroxy-ethinyl estradiol, is further transformed into a highly reactive compound that can irreversibly bind to microsomal protein.[36, 37] The oxidation of the ethinyl group by cytochrome P-450 enzymes leads to very reactive intermediates that can covalently bind to proteins or react with the prosthetic heme group, resulting in an inactivation of the enzyme.[38, 39] During the latter

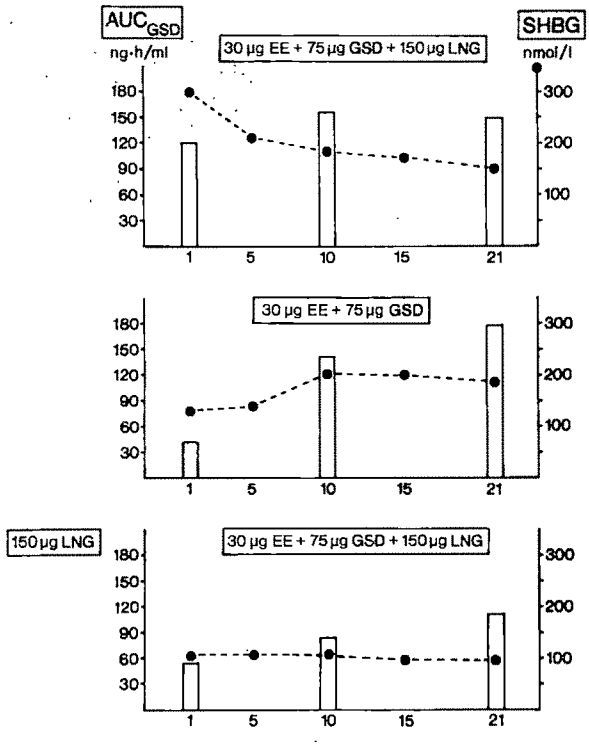

Fig. 16. Areas under the time versus serum concentration curves between 0 and 24 hours of gestodene and serum concentrations of sex hormone–binding globulin during one cycle of treatment with 30 µg of ethinyl estradiol + 75 µg of gestodene + 150 µg of levonorgestrel, during one cycle of treatment with 30 µg of ethinyl estradiol + 75 µg of gestodene and during one cycle of treatment with 30 µg of ethinyl estradiol + 75 µg of gestodene + 150 µg of levonorgestrel after pretreatment with 150 µg levonorgestrel for 7 days in one woman. *GSD,* Gestodene; *LNG,* levonorgestrel.

reaction, which is called mechanism-based inactivation or suicide inhibition of cytochrome P-450–dependent mixed function oxidases, alkylated porphyrins are formed.[40, 41] An increase in urinary excretion of porphyrins has been observed in women during treatment with oral contraceptives.[42, 43] The reactive intermediate after oxidation of the ethinyl group can also react with itself, forming a D-homo-steroid by dilatation of the 5-ring D to a 6-ring. Such metabolites of ethinyl estradiol (D-homo-estradiol) and gestodene have been isolated from urine. Moreover, a high rate of irreversible protein binding of gestodene (= Δ15-d-norgestrel) in the microsomes of rat liver has been previously reported.[44]

Further possible interactions of oral contraceptive steroids with metabolizing enzymes include conjugation of ethinyl estradiol, since estrogen glucuronidation by liver microsomes has been found to be inhibited by ethinyl estradiol.[45] It is known that a major part of ethinyl estradiol, taken orally, is metabolized in the intestinum. Therefore it remains to be elucidated whether an inhibition of intestinal enzymes by contraceptive steroids may play a role. Because it has been demonstrated that progesterone or certain of its metabolites may decrease oxidative drug metabolism,[46] the possible interaction of progesterone derivatives with these enzymes must be the subject of further investigations.

Intraindividual and interindividual variations. The large intraindividual and interindividual variations in the serum concentrations of ethinyl estradiol during treatment with ethinyl estradiol/desogestrel and ethinyl estradiol/gestodene are in agreement with previously reported results of the pharmacokinetic studies on oral contraceptives.[5, 6, 28, 31, 47-50] The reasons for the variability have not as yet been clarified. Multicenter studies demonstrated large variations in the pharmacokinetics of ethinyl estradiol in different countries, but also within the same locality, which indicates that ethnic factors probably play no major role.[47, 51] After adjustment for race, age, weight, height, blood pressure, cigarette and alcohol consumption, or life-time use of oral contraceptives, 72% of the variability in the ethinyl estradiol levels remained unexplainable.[5] Similar to our findings, no influence of body weight could be observed.[28] Contrary to this, a genetic or acquired predisposition seems to have an important influence, since during 12 cycles of treatment with ethinyl estradiol/desogestrel or ethinyl estradiol/gestodene, most of the women showed a relatively stable pattern. However, the large intraindividual variations which were in the same range as the interindividual differences, indicate an important influence of thus far unknown short-lasting factors. In all probability, alterations in the metabolic capacity of the intestinum and liver from day to day appear to be causative, since large variations in the half-life of ethinyl estradiol between 2 and more than 30 hours and in the elimination rate constant between 0.02 and 0.25 have been reported.[23, 50, 51] It has been suggested that the pronounced variability is typical for drugs with a first-pass effect. Ethinyl estradiol is already conjugated to a considerable extent in the intestinal mucosa and the liver.[52] Contrary to this, levonorgestrel, 3-keto-desogestrel, and gestodene are not subject to a first-pass effect. Nevertheless, the average intraindividual and interindividual coefficients of variation of 3-keto-desogestrel and gestodene were in the same range as those of ethinyl estradiol. Similar results have been reported on norethisterone and levonorgestrel.[23, 49, 53, 54] Because of an enhanced enterohepatic circulation, ethinyl estradiol levels may rise secondarily between 5 and 12 hours after food intake.[55] On the other hand, progestogens undergo nearly no enterohepatic circulation because their main metabolic steps are reduction or hydroxylation, which results in a loss of hormonal activity. Moreover, in our study the women fasted overnight. There was no correlation between serum con-

centrations of ethinyl estradiol and those of gestodene or 3-keto-desogestrel. Therefore the coefficient of the ratios between ethinyl estradiol and 3-keto-desogestrel or ethinyl estradiol and gestodene exceeded those of AUCs of the steroids. No correlation between ethinyl estradiol and the respective progestogens has previously been observed during treatment with oral contraceptives.[23, 50]

Environmental factors, such as diet, smoking, and stress, influence oxidative metabolism in humans and animals. Change in posture from lying to standing upright may alter metabolic clearance of androstenedione.[56] The serum level of progesterone is decreased by 34%, and metabolic clearance is increased within 1 hour after a meal, possibly because of enhanced splanchnic blood flow.[57] A high-protein diet leads to an increase in antipyrine oxidation and to an enhancement of 2-hydroxylation of estrogen.[58, 59] Contrary to this, a high-protein diet decreases Δ4-5α-reduction of testosterone.[60] In male chimpanzees, a high-fat diet reduces 2-hydroxylation of estradiol by 50%.[61] An increase in 2-hydroxylation of estradiol was induced by weight loss.[62]

Physical stress diminishes the metabolic clearance rate of estradiol by 80% within a few minutes, which can be explained only partly by a decrease in hepatic blood flow.[63] In male rats the metabolism of drugs and steroids is reduced 48 hours after stress, whereby somatotropic hormone and adrenocorticotropic hormone but not adrenal hormones play an essential role.[64, 65] It is unknown whether the pituitary gland is directly involved in the control of hepatic steroid metabolism in humans.

Pharmacodynamics. During the 12 months of treatment with ethinyl estradiol/desogestrel and ethinyl estradiol/gestodene, no significant difference was found in most of the metabolic serum parameters.[66, 67] This can be explained by the antagonistic effect of the estrogen and progestogen components on lipids, lipoproteins, and most of the hepatic proteins. The effect of higher ethinyl estradiol levels during treatment with ethinyl estradiol/gestodene may be counteracted by a more pronounced action of the high gestodene levels, resulting in a similar net effect such as during intake of ethinyl estradiol/desogestrel. It has been demonstrated that oral contraceptives containing 30 μg ethinyl estradiol and 150 μg of levonorgestrel or 50 μg of ethinyl estradiol and 250 μg of levonorgestrel produced qualitatively and quantitatively similar effects on lipid metabolism, ceruloplasmin, and antithrombin III.[68] The only differences found in our study were significantly higher serum concentrations of corticosteroid-binding globulin and cortisol[8] and a more pronounced increase in triglyceride levels[67] during treatment with the gestodene-containing pill. Corticosteroid-binding globulin is influenced only by the estrogen component and not by progestogens. Moreover, the effects of potent sex steroids are not far from the dose-dependent end-point, and the duration of treatment appears to be more important for the resulting effect on serum parameters than the differences in steroid serum levels. Although steroid levels show large intraindividual variability, the hepatic parameters reflect an integral effect of the steroids over time. This was confirmed in our study by the differences in the corticosteroid-binding globulin and cortisol levels, which became more pronounced during the sixth and twelfth cycles.[8]

In a recent paper the influence of the slope of serum levels of ethinyl estradiol and norethisterone calculated from single determinations before and 1 hour after intake of the last tablet of the third, sixth, and ninth treatment cycles on changes in outlier status for lipids and lipoproteins has been observed.[69] However, the authors did not report on a correlation between steroid levels or slopes and the parameters of lipid metabolism in the total group of volunteers.

In our study no correlation could be found between individual ethinyl estradiol and progestogen levels and the occurrence of intermenstrual bleedings. Neither women with high ethinyl estradiol and low 3-keto-desogestrel or gestodene levels nor women with low estrogen and high progestogen levels showed a consistent bleeding pattern. This was true for the first treatment cycle and also for the whole treatment period when the average of 12 AUCs of ethinyl estradiol and gestodene or 3-keto-desogestrel was compared with the bleeding pattern of each woman. The cause of irregular bleedings has not yet been clarified. It is known that missing one pill during a treatment cycle results in a 13- to 16-fold increase in the risk of intermenstrual bleeding.[70] This means that a pronounced deficiency of circulating steroids on one day may cause bleeding. A similar effect may be produced when relatively high levels (e.g., of the progestogen) during the course of a cycle are superseded by very low levels on one or more days because of the effect of as yet unknown factors on pharmacokinetics. Such an effect cannot be substantiated by single determinations of steroid levels and even not by the investigation of pharmacokinetics on 3 of 21 days of treatment, but reliable data are needed during the whole cycle.

Prodrugs: Advantage or disadvantage?

Jürgen Hammerstein, MD
Berlin, West Germany

Our knowledge of the peculiarities of prohormones is rather limited, both pharmacologically and clinically. Generalizations cannot be made except that the lapse of time until peak blood values of the active drug have been reached are always greater after intake of the prodrug than after intake of the drug. This finding is presumably of no clinical importance. If pharmacokinetic differences are limited to the phase of distribution, bioequivalence may be assumed. If, on the other hand, the area under the curve during the elimination phase is smaller for the prodrug than for the drug, the potency of the former should be decreased. A shift in the spectrum of endocrine actions as a result of the biotransformation of the prodrug into the active drug is rather the exception than the rule, and so is a change in side effects. If there are major differences in this respect, metabolic pathways in addition to those leading to the respective active drug must also be taken into consideration. (Am J Obstet Gynecol 1990;163:2198-203.)

Key words: Contraceptive prodrugs, estrogens, progestogens

Hormonal prodrugs (prohormones) exert their specific effects only after biotransformation. The development of the first hormonal drugs of this sort dates back to the 1950s, when the concept of prodrugs was still unknown. Thus, lynestrenol (LYN) appeared at that time to be a potent progestogen by itself, despite lacking an oxygen in 3-position—a configuration that had already been recognized at that time to be a prerequisite of the endocrine activity of a given steroid hormone. The prodrug nature of LYN was disclosed only years later when this steroid was found to be quickly biotransformed into norethisterone before action. The same was found to be true for other members of the estrane category, that is, for norethisterone acetate (NETA) and ethynodiol diacetate (EDD). Among the gonanes, desogestrel and norgestimate are prohormones, and even cyproterone acetate (CPA), a progestogen of the pregnane category, may be considered a borderline prohormone.

Mestranol is another example of an old pharmaceutical compound, the prodrug nature of which was not detected before the receptors came into play years later. By definition, pure prodrugs like mestranol, LYN, EDD, and desogestrel do not interact with the receptor at all. There are also incomplete prodrugs such as NETA and norgestimate, with receptor binding affinities being more or less limited (Table I).

Whether the use of prodrugs instead of drugs is an advantage will be discussed under pharmacokinetic, quantitative, endocrine, and metabolic aspects. This issue can be properly investigated only if the active drug is available for comparison, as for example, norethisterone (NET) or ethinyl estradiol (EF_2). Altogether, relevant data are sparse, and only occasionally are true comparisons done.

Table I. Relative binding affinities of various progestational drugs, prodrugs, and intermediates

	Receptor	
	Progesterone	*Androgen*
	(Promegestron R 5020 = 100)	*(Metribolon R 1881 = 100)*

Norgestrel-17-β-acetate	135	—
Norgestrel-3-oxim	10	—
Levonorgestrel	150	30

Data from Kuhl H. Wien Med Wschr 1987;137:433-40.

Concerning the estranes, to begin with the oldest category of oral progestational compounds, the pharmacokinetic data are scattering at a wide range (Table II). As the only reproducible pharmacokinetic peculiarity, time interval to peak (T_{max}) of NET after oral ingestion of 1 mg of NETA, EDD, or LYN occurs about an hour later than that after oral intake of NET itself. Thus, biotransformation of these prodrugs into NET obviously takes at least 1 hour. Furthermore, half life

between 24 and 27 hours after oral intake of 5 mg LYN turned out to be definitely longer than after 5 mg NET in the five patients tested.[1]

The areas under the plasma curve (AUC) of NET after ingestion of 0.3 mg NET and 0.5 mg LYN were found to be almost equal. Compatible AUCs were also seen after oral intake of 0.7 mg NET and 1.0 mg LYN. At a daily dose of 5 mg of either drug, the AUC between 0 and 24 hours was about 20% higher after NET than after LYN.[1,2] Thus, biotransformation of LYN into NET does not appear to be complete.

As long as 120 hours after administration of carbon 14–labeled LYN, plasma radioactivity is still rather high, which again indicates that a minor portion of LYN may escape metabolization into NET. Furthermore, because a shift occurs of T_{max} to longer time intervals with increasing oral doses of LYN, it is tempting to assume that the capacity of the liver to transform LYN into NET is limited. In other words, high-dose LYN medications might constitute a liver burden.[3]

After three decades of widespread use of LYN for contraceptive as well as gynecologic purposes, evidence is still lacking as to whether any clinical impact exists in the pharmacokinetic differences between LYN and NET. This is in particular true for the somewhat longer biologic half-life and the slightly lower AUC after oral intake of LYN than after that of NET. Thus, the use of LYN instead of NET implicates some uncertainties without clear-cut advantages or disadvantages.

No biologic tests are available to measure with any degree of reliability the progestational potency of drugs in women. As shown in Table III, results in this field are rather controversial. Thus, it cannot be stated which is more potent, the prodrugs of NET or the drug itself, to say nothing about ranking. The progestational strength of EDD, for example varies relatively to NET by factor 20, despite the fact that the AUCs have been reported to be rather similar.[4]

Norethynodrel is another member of the estrane family that needs attention. The unchanged drug can be detected in the plasma for only 30 minutes.[5] Conversion into NET occurs among other sites in the endometrium and myometrium, with a degree of activity being higher during the proliferative than during the secretory phase.[6,7] It is generally believed that this drug does not exert its progestational activity before transformation into NET. In contrast to NET and the other estranes, however, this prohormone is free of androgenic activity. Also, it possesses a much stronger estrogenic potency than the other estranes, as was demon-

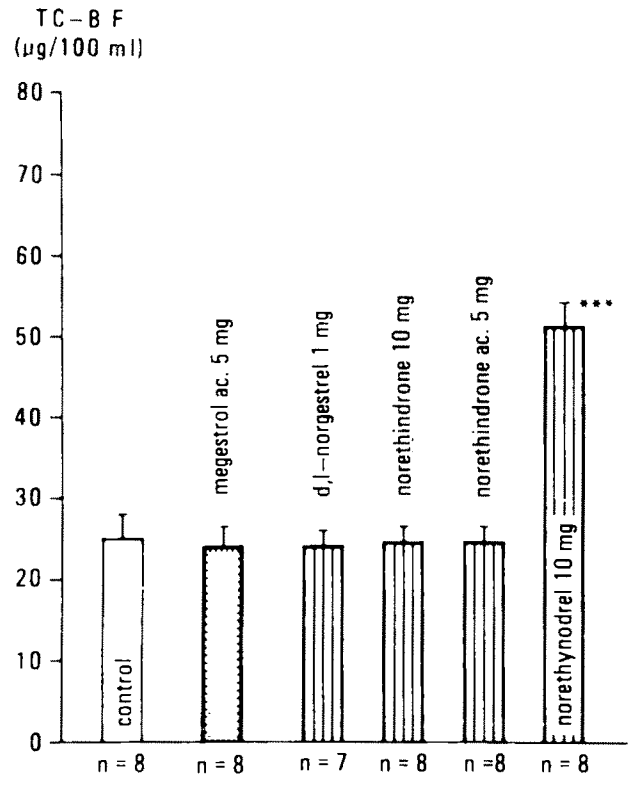

Fig. 1. Cortisol-binding capacity of transcortin *(TC-BF)* as influenced by various contraceptive progestogens administered successively for 14 days each in eight (seven) women with total gonadal insufficiency. (From Schwartz U, Hammerstein J. Acta Endocrinol 1974;76:159-71. By permission.)

strated, among other things, on the basis of the mouse uterine test.[8] When transcortin binding capacity was used as an indicator of estrogenicity, the same was also shown in women: out of five progestogens, norgestimate was the only one to increase this plasma parameter to an extent similar to that of EE_2 (Fig. 1). Thus, norgestimate must be biotransformed not only into NET but also along other routes, unless one distrusts the producer's affirmation that this first orally applicable progestogen was free of estrogenic contaminations. Ethynodiol, the metabolic intermediate between norgestimate and NET, should be without relevance in this respect because it is also an intermediate of LYN.

Desogestrel must be biotransformed through 3-α-OH-desogestrel and 3-β-OH-desogestrel into 3-ketodesogestrel to act as a progestogen at the target cell level (Table I). This transformation is a matter of approximately half an hour; thereafter, plasma levels of 3-ketodesogestrel are almost identical irrespective of whether desogestrel or 3-ketodesogestrel has been administered at the same dosage level (Fig. 2). Nothing has become known as to whether 3-ketodesogestrel in clinical terms is as good a contraceptive progestogen as desogestrel and whether it is tolerated equally well.

Informations are limited concerning norgestimate. No doubt this progestogen of the gonane category is biotransformed into levonorgestrel, to what degree, however, is a matter of debate. In particular, it is still unknown whether norgestimate itself and/or its transformation products norgestrel-3-oxim and norgestrel-17-β-acetate are also endocrinologically active because they bind also to the receptors more or less tightly (Table I).

The field of progestational agents should not be left without—at least briefly—mentioning cyproterone acetate (CPA). CPA may be classified as a borderline prodrug because the major part is biotransformed into the 15-β-OH-analogue (15-OH-CPA), which still—like the parent substance—exerts progestational as well as antiandrogenic actions (Fig. 3). To judge from animal experiments, the progestational and antiandrogenic potencies are balanced much better with 15-OH-CPA than with the parent compound, in which the former property outweighs the latter considerably.[9] 15-OH-CPA is thus an example of a "drug" that appears to be advantageous over the "prodrug." This track has not been followed further by the producer, unfortunately.

The vivid debate in the past as to whether mestranol and EE_2 are equal both in quantitative and qualitative respect has faded away in recent years without coming to a definite conclusion. Because various drug regulatory authorities felt the two estrogenic drugs were bioequivalent and the majority of pharmaceutical companies believed the opposite to be true, mestranol has not been introduced into low-dose oral contraception. This issue, therefore, is only of academic interest today.

To judge from EE_2 plasma levels after oral ingestion of the two estrogenic drugs, the bioavailability of EE_2 has unanimously been found to be higher than that of mestranol. Also, T_{max} was distinctly shorter after EE_2 than after mestranol administration.

According to unpublished data of this meeting, the area under the EE_2 curve after mestranol ingestion is only two thirds that after EE_2 intake, and the same appears to be true for the peak values.[10]

This is in accord with experimental data of Bolt and Bolt,[11] who determined the in vivo demethylation rate of mestranol to EE_2 to be 53.7%, with the residual mestranol undergoing hydroxylation and conjugation before elimination. As another difference, the metabolic clearance rate of mestranol was found to be 1741 ± 393 L/24 h; for EE_2 it was 1345 ± 221 L/24 h.[12] The clearance rates of the metabolites of radioactive mestranol, on the other hand, were shown to be slower than those of the metabolites of radioactive EE_2.[13]

In keeping with these findings are data from their own laboratory on cortisol binding capacity of transcortin as influenced by these two estrogens after oral application. When using this parameter, mestranol had only two thirds the potency of EE_2 (Fig. 4). Histometric

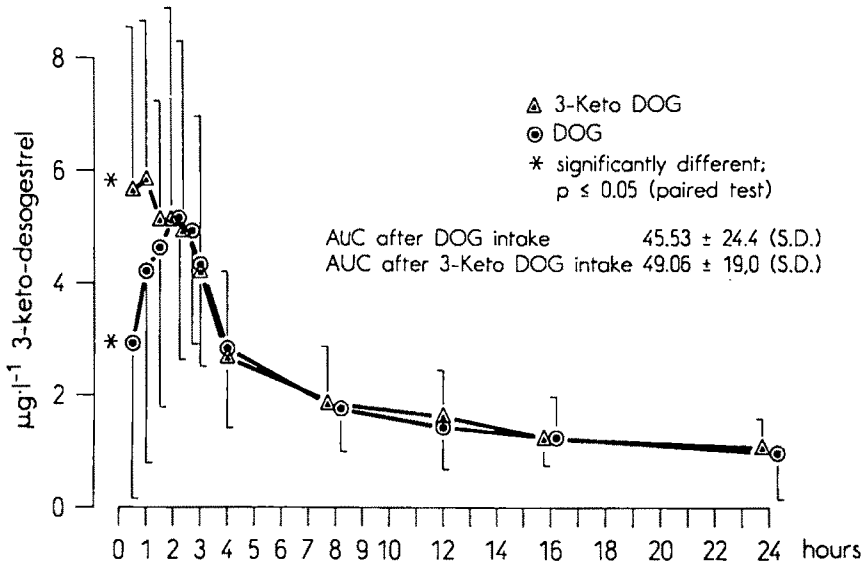

Fig. 2. Pharmacokinetics of 3-ketodesogestrel after single administration of 150 gm desogestrel or 150 gm 3-ketodesogestrel together with 30 gm EE_2 each. (Modified from Hasenack HG, Bosch AMG, Käär K. Contraception 1986;33:591-6, by permission of the copyright holder, Butterworth-Heinemann.)

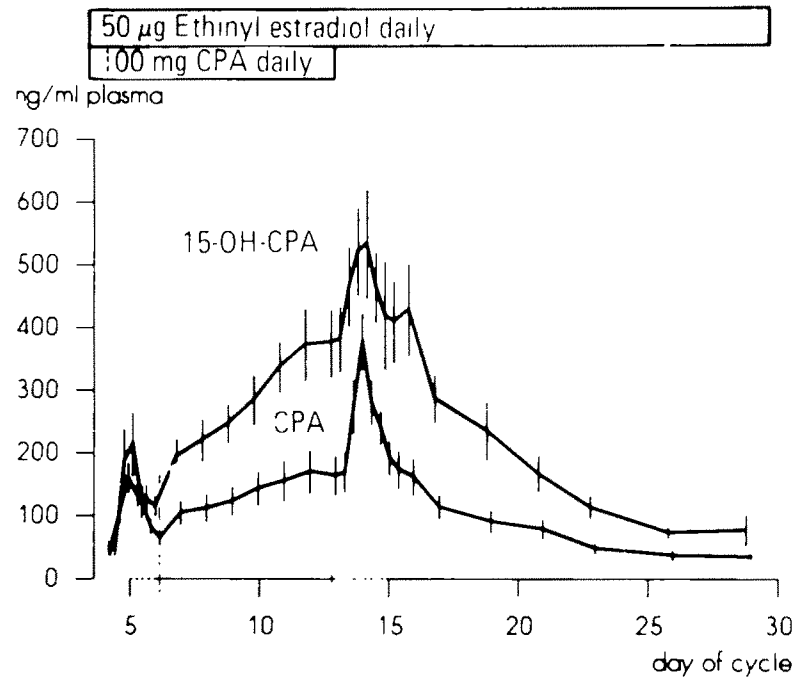

Fig. 3. Pharmacokinetics of CPA and its 15-β-OH-metabolite as measured by high-performance liquid chromatography in the course of the reverse sequential therapy in seven androgenized patients. Data are expressed as mean ± SEM, diurnal course on day 5 and 15 of cycle. (From Hammerstein J. Antiandrogens: clinical aspects. In: Orfanos C, Happle R, eds. Hair and hair diseases. Berlin, West Germany: Springer, 1990:827-86, by permission.)

as well as histologic endometrial findings are also well in accordance with the above.[14, 15]

No differences in potency between mestranol and EE_2, on the other hand, were found by others, based either on vaginal cytology,[16] on inhibition of gonadotropin secretion,[17, 18] on suppression of ovulation, or on endometrial findings.[19, 20] The lack of differences in potency between the two estrogens in these investigations might have been caused by estrogen dosage being too high for the establishment of an appropriate dose-response relationship under in vivo conditions.

In clinical terms, a clear-cut distinction between the

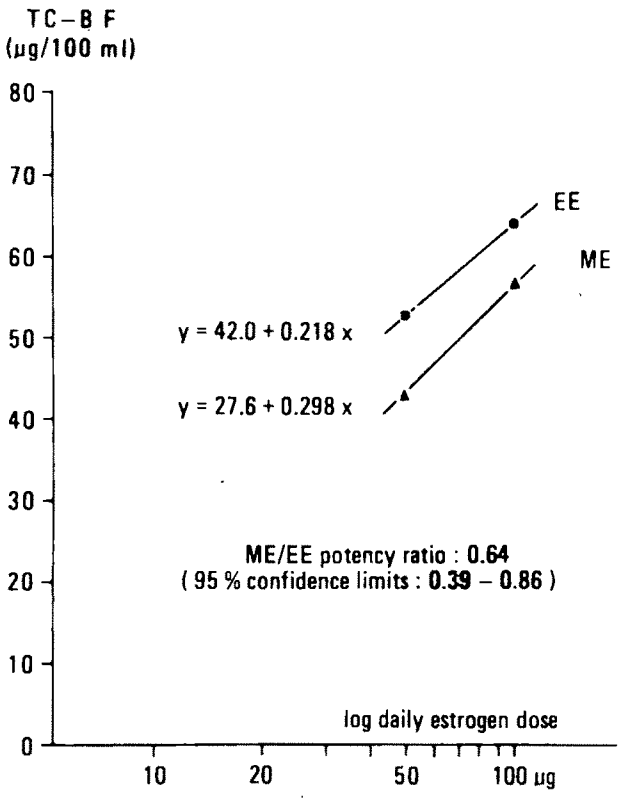

Fig. 4. Cortisol-binding capacity of transcortin as influenced by mestranol *(ME)* and ethinyl estradiol *(EE)*, successive measurements after 14 days of administration of each of the two estrogens at two dosage levels in four women with total gonadal insufficiency. (From Schwartz U, Hammerstein J. Acta Endocrinol 1974;76:159-71. By permission.)

two oral contraceptive estrogens cannot be made. According to the well-known British-Scandinavian study of Inmann et al.,[21] the incidence of thromboembolism appears to be positively correlated with the dose of the estrogen component of the pill, with no difference between EE_2 and mestranol being discernible. Contrary to earlier suggestions, the influence of the two estrogenic drugs on carbohydrate metabolism compares well, and so does their influence on triglycerides.[22, 23]

Gastrointestinal disease and oral contraception

Jürgen P. Hanker, MD
Münster, West Germany

Oral contraceptive steroids play a major role in modern family planning. With the present tendency to decrease the doses of both estrogens and progestogens, any factor that reduces the bioavailability of the lower-dose preparations may have an impact on contraceptive protection. Although ethinyl estradiol, the most commonly used oral estrogen, is liable to an enterohepatic circulation as unchanged drug, the commonly used progestogens are not. At present, no convincing evidence exists in the human subject that disruption of the enterohepatic circulation by antibiotics or antacids does reduce contraceptive efficacy of the pill. Oral contraceptive steroids are mainly absorbed from the small bowel, and contraceptive efficacy depends on its absorptive capacity. Enhanced passage of gastrointestinal contents or impaired absorption may thus contribute to contraceptive failures in patients who have chronic inflammatory disease, diarrhea, ileostomy, or jejunoileal bypass. (Am J Obstet Gynecol 1990;163:2204-7.)

Key words: Oral contraceptive steroids, gastrointestinal disease, contraceptive failure

Oral contraceptive steroids have now been in widespread use for more than two decades. It is estimated that worldwide these drugs are regularly taken by more than 60 million women.[1] Over the past few years, a large body of information has appeared dealing with the clinical pharmacology of these substances in young and healthy women. In contrast, the knowledge about the pharmacokinetics of oral contraceptive steroids in disease states is only limited. To reduce toxicity of oral contraceptive preparations, both estrogenic and progestogenic components have gradually been reduced. Most contraceptive formulations now contain <50 μg estrogen and 1 mg progestogen or less. Any factor that reduces the bioavailability of these lower-dose preparations may thus become very relevant in terms of contraceptive protection. Dietary factors, gastrointestinal disturbances or diseases, or drugs that interact with contraceptive steroids and thereby reduce their efficacy may constitute some of these factors. Because oral contraceptive users undergo prolonged periods of steroid ingestion, they most likely experience dietary or gastrointestinal problems or coadministration of an additional drug at some time during oral contraception.

Enterohepatic circulation of oral contraceptive steroids

Oral contraceptive steroids are of two types: estrogens and progestogens. Of the estrogens, ethinyl estradiol is the most important. Less commonly used is mestranol, the methylated derivative of ethinyl estradiol.

Ethinyl estradiol is rapidly absorbed in humans, and peak concentrations of the drug are reached by 120 minutes after variable dosing.[2-9] After a single oral dose of 50 μg, peak concentrations of ethinyl estradiol range from 100 to 200 pg/ml.[10] During long-term treatment with 30 to 50 μg ethinyl estradiol daily, a plasma concentration range of 6 to 190 pg/ml is found.[11]

Ethinyl estradiol undergoes considerable first-pass metabolism,[12] of which the chief reaction is sulfate conjugation in jejunal mucosa.[13] Gut wall conjugation accounts for about 65% of the first-pass elimination of the drug.[14] Thus bioavailability of an oral preparation relative to an intravenous one is 40% on average; the interindividual variation, however, is great (20% to 65%).[2] Preliminary data suggest that gut wall metabolism of ethinyl estradiol is reduced in patients with celiac disease, thereby increasing the bioavailability of the steroid.[13] However, the clinical relevance of this observation has yet to be confirmed.

Because of the 17α-ethinyl group, ethinyl estradiol is relatively resistant to metabolism by 16α-hydroxylation, which in the case of estradiol itself leads

to the formation of 16α-hydroxyestrone and estriol. Thus the substance is metabolized chiefly by aromatic hydroxylation, resulting in the most important ring, A metabolite 2-hydroxy-ethinyl estradiol.[15, 16] Additionally, ethinyl estradiol may be hydroxylated in the C_4, C_6, and C_{16} positions,[17, 18] and 6α- and 16β-hydroxy-ethinyl estradiol are formed. These metabolites are conjugated chiefly with glucuronide.[19]

Ethinyl estradiol is excreted in bile and urine principally as glucuronide or sulfate conjugates.[20] Conjugation takes place largely on the 3 position. After excretion in the bile,[21] these conjugates reach the gut lumen and are hydrolyzed by enzymes present in gut bacteria. Thus the original compound is liberated and may be reabsorbed.[22] This mechanism forms the basis for an enterohepatic circulation of ethinyl estradiol as an unchanged drug. At present it is not clear to what extent the enterohepatic recirculation contributes to the overall plasma concentration profile of ethinyl estradiol in the human female.[10] If one assumes that it does, any disruption of this mechanism should increase the risk of contraceptive failure.

Oral treatment with antibiotics would be expected to interfere with enzymatic hydrolysis and hence reduce or abolish steroid reabsorption from the gut. It is the unconjugated steroid only that can be reabsorbed across the intestinal mucosa. Reports exist in the literature that link oral antibiotic therapy to contraceptive failures in oral contraceptive users.[10, 23-26] However, clinical studies with ampicillin have failed to demonstrate any significant interaction between the antibiotic and oral contraceptive steroids.[27-30]

Prolonged ampicillin therapy will rapidly lead to resistant organisms in the gut. Resistance to ampicillin may develop within 5 to 6 days of therapy.[31] Any significant effect on ethinyl estradiol metabolism may, therefore, have been missed if monitoring started after 2 weeks' therapy. However, continuous observation during a 5-[27] or 7-day regimen[28] of ampicillin also did not reveal any substantial effect on steroid metabolism. Similar results have been obtained with erythromycin or trimethoprim in human subjects.[27] At present, no convincing evidence exists that antibiotics substantially interfere with oral contraceptive steroids at the level of the enterohepatic circulation. However, other mechanisms, such as interference with steroid-degradating enzymes in the liver, cannot be ruled out; these will be dealt with separately.

Use of antacids for several specific and nonspecific gastrointestinal complaints is widespread. Self-administration of antacids is a common phenomenon. Antacids are known to interact with several therapeutic agents, thereby reducing their bioavailability.[32] In vitro adsorption of synthetic sex steroids on antacid magnesium trisilicate has been demonstrated.[33] However, in vivo bioavailability of contraceptive steroids was unaffected by concomitant antacid administration. In 12 women who were given an antacid (magnesium trisilicate, 0.5 gm, and dried aluminium hydroxide, 0.25 gm) and a contraceptive pill (containing ethinyl estradiol, 30 μg, in combination with either norethisterone-acetate, 1 mg, or levonorgestrel, 150 μg) simultaneously, no change in the total bioavailability of any steroid was seen.[34] Moreover, no delay in the time taken to reach peak concentration was seen. The authors conclude that clinically significant interactions between oral contraceptives and antacids appear to be unlikely in the in vivo situation.

Mestranol is less commonly used as the estrogenic component of contraceptive steroid formulations. In the body, mestranol is rapidly converted to ethinyl estradiol by hydrolysis,[15] and the estrogenic effect is almost entirely caused by the demethylated compound. Mestranol and ethinyl estradiol can be regarded as equipotent.[35] After demethylation, mestranol is metabolized in a fashion similar to that with ethinyl estradiol, including enterohepatic recirculation.

The most commonly used progestogens in oral contraceptives are norethisterone, levonorgestrel, desogestrel, and less commonly, the pregnane derivatives cyproterone acetate and chlormadinone acetate. The progestogens norethynodrel, ethynodiol diacetate, lynestrenol, and norethisterone acetate are metabolized to norethisterone and become active as such. Desogestrel has to be converted to its active compound, 3-keto-desogestrel, and norgestimate is active after conversion to norgestrel-17β-acetate and levonorgestrel.

All of the steroids are well absorbed in human subjects, with levonorgestrel being completely bioavailable and norethisterone 70% available on average.

Norethisterone is chiefly metabolized by saturation of the double bond and reduction of the 3-keto group to a hydroxyl group. The metabolic pathways of levonorgestrel include 2α hydroxylation, 3α-5β reduction, 16β hydroxylation, glucuronidation of the 16β-hydroxy metabolite, and direct sulfate conjugation.[10] It is apparent that the progestogens have to be reduced at the 3 position before conjugation. Because little evidence exists for direct conjugation at the 17 position, the progestogens do not undergo enterohepatic recirculation as unchanged drugs. Any disruption of this latter mechanism would therefore have no impact on contraceptive efficacy.

Chronic inflammatory bowel disease and oral contraceptive steroids

Ample evidence exists of an association between chronic inflammatory bowel disease and smoking habits. Patients with ulcerative colitis tend to be nonsmokers,[36-40] and patients with Crohn disease tend to be

smokers.[36, 41] However, evidence also exists that women taking oral contraceptive steroids have an increased risk of Crohn disease.[42-44] According to Vessey et al.,[45] the use of oral contraceptives is more strongly associated with ulcerative colitis than with Crohn disease. A direct correlation between the duration of oral contraceptive use and the relative risk of Crohn disease has been demonstrated.[46] Accordingly, the relative risk is increased eight-fold after contraceptive pill use for more than 5 years; this high risk is normalized when at least 4 years have elapsed since the last pill use.

The pathogenetic role of oral contraceptives in chronic inflammatory bowel disease, if any exists, remains obscure. The observation that colonic Crohn disease is particularly associated with the use of contraceptive steroids suggests a vascular basis for the lesions. Kirsner and Shorter[47] proposed a role for transient insults, including ischemia, in the development of inflammatory bowel disease. Acute segmental colitis associated with pill use have been interpreted by ischemic episodes[48, 49] including the mesentery.[50-52]

The belief has been widespread that women who take oral contraceptive steroids and who have diarrhea are at risk of contraceptive failure. Women with an ileostomy might be at even higher risk because of an enhanced intestinal passage of gastrointestinal contents as well as the loss of enterohepatic steroid recirculation. In patients having undergone ileostomy for ulcerative colitis involving only the colon, the bioavailability of ethinyl estradiol and levonorgestrel (after a single oral dose of 50 μg of ethinyl estradiol and 250 μg of levonorgestrel) was not different from that of control subjects.[53] Similar results were obtained in patients with unoperated ulcerative colitis.[54] However, plasma levonorgestrel levels were reduced after either conventional ileostomy or proctocolectomy with construction of a continent ileostomy. The lowest levels of levonorgestrel were recorded in patients with the largest (10 and 35 cm) bowel resections. It is suggestive to explain these results by a reduced overall absorptive capacity caused by the loss of 35 to 45 cm of terminal ileum needed for construction of the pouch. However, direct administration of levonorgestrel into the pouch showed that the ileal mucosa had retained its absorptive capacity in spite of morphologic changes[55] and bacterial overgrowth.[56] The exact mechanism leading to reduced bioavailability under these conditions remains obscure.

Jejunoileal bypass has long been standard surgical procedure in the treatment of morbid obesity. The rationale for this operation is to bypass the major part of the small bowel to reduce its absorptive capacity.

In seven morbidly obese women, jejunoileostomy end side had been performed, leaving 37 cm of jejunum and 12.5 cm of ileum in continuity. After an oral load with either 3 mg of norethisterone or 250 μg of levonorgestrel, a significantly reduced bioavailability of either steroid was observed.[57] These data clearly demonstrate that oral contraceptive steroids are mainly absorbed in the small bowel and that contraceptive efficacy is dependent on its absorptive capacity. In case of small bowel diarrhea, contraceptive failure is likely to occur. In most instances, however, diarrhea is of colonic origin and should therefore not affect contraceptive safety.

Influence of oral contraceptives on drug therapy

Alexander T. Teichmann, Prof. Dr. med.
Göttingen, West Germany

Interferences between drugs and oral contraceptives are considered to alter pharmacokinetics and thus the efficacy of steroidal hormones. It should be noted, however, that steroids can also modify the metabolism and pharmakodynamic effects of various substances. To the present knowledge, phase I (i.e., oxidation, demethylation) and phase II reactions (conjugation) are concerned. Drugs sharing those enzymatic systems with oral contraceptives experience either an increase in bioavailability by inhibition of oxidative metabolism or undergo accelerated elimination by induced conjugation. Such interaction may be of practical interest in subjects who take oral contraceptives and are simultaneously treated with antidepressants, antihypertensives, insulin, synthetic glucocorticoids, theophylline, and caffeine. (Am J Obstet Gynecol 1990;163:2208-13.)

Key words: Oral contraceptives, drug interactions, pharmacokinetics, pharmacodynamics

Although oral contraceptives (OC) are among the most widely used drugs in the world whose effects and side effects have been extensively investigated, their pharmacology still remains a perplexing field of multivariate processes. The biochemical and physiologic actions of estrogens and gestagens are not simply additive when given in combination, and their interactions with other drugs lead to an even greater degree of complexity. The following attempt to review the effects of OCs on the pharmacology of other drugs will inevitably be all but satisfactory not only because it is made by a gynecologist but also because a reviewer's task is to condense and stratify information rather than to present all details available.

Three major principles of drug interactions exist, of which the chemical reaction between drugs is unlikely to apply to steroid hormones. OCs can, however, influence pharmacokinetics, particularly through protein binding patterns, and metabolism, and they can also interfere with pharmacodynamics.

Most commonly interactions of OCs with other drugs will take place if phase I reactions are concerned. It is well known that cytochrome systems P-450 and P-448 can be inhibited by OCs either directly or by competition. Moreover, phase II reactions, namely, conjugation with acids, are positively influenced by OCs through enzyme induction. Orally administered ethinyl estradiol (EE) exerts a strong stimulatory effect on protein synthesis, which is partly opposed by gestagens. Finally, receptor-mediated hormonal actions may interfere with wanted or unwanted drug effects of hormonal and nonhormonal agents.

Before I discuss groups of commonly prescribed pharmaceutical products in detail with respect to the interfering actions of OCs, a few basic remarks are necessary:

1. Combined OCs represent a homogenous group of hormonal agents as far as the type of estrogen and the oral route of administration are concerned.
2. Combined OCs are heterogenous with regard to the doses of EE and the type and dosage of the gestagen.
3. The biologic effects of OCs do not depend solely on their composition and route of administration, but to a large extent depend on individual factors such as age (metabolic activity), individual pharmacokinetics, dietary habits, body mass, physical activity, neuroendocrinologic conditions, and numerous others.

These characteristics of OCs and their actions in individual organisms will be largely omitted in the following summary of our knowledge on how OCs modify the effects of other drugs. Although I am quite aware that simplifications may sometimes lead to wrong conclusions, limited space demands this sacrifice for a more pragmatic approach (Table I). Contradictory findings in the following studies cited may be explained by factors such as differences in OC composition and individual conditions.

Analgesics belong to the most frequently taken drugs available without medical prescription, and thus it is not remarkable that they are often taken during hormonal contraception. Phenazone is mainly metabolized by oxidation. Its halflife is prolonged, and its clearance rate is reduced by OCs as a result of delayed hydroxylation. Similar conclusions were reached by the authors of other studies investigating the effects of EE on pethidine, a synthetic morphine-analog. Morphine undergoes conjugation with glucaronic acid, and enzy-

Table I. Influence of OCs on the pharmakinetics of commonly prescribed drugs

Type	*Generic*	*Bioavailability*		*Authors*
		Augmented	*Decreased*	
Analgesics	Phenazone	Inhibited oxidation		Teunissen et al., 1982[28]
		Decreased clearance		Abernethy et al., 1981[29]

matic process that is stimulated by OCs, leading to enhanced metabolism and thus inactivation of this drug. In rat liver preparations, however, as shown by Carter et al.,[1] ethylmorphine metabolism is reduced by inhibition of its demethylation in the presence of OCs. The ability of OCs to induce enzymatic conjugation, namely, with glucuronic and sulfuric acid, seems to be the mode of action by which the metabolism of paracetamol and

aspirin is enhanced. In particular, glucuronidation accounts for 90% of the biotransformation of paracetamol. Because this substance is also metabolized by oxidation, the corresponding influence of OCs on this reaction is of interest. However, the findings reported by Miners et al.[2] and Mitchell et al.[3] are contradictory. It may be of importance to note that Gupta et al.[4] found the influence of OCs on aspirin glucuronidation to decrease with the time of OC use. Morphine shows decreased bioavailability as a result of stimulatory effect on conjugation with glucuronic acid, whereas in rat liver preparation, the demethylation of ethylmorphine seems to be inhibited. Pethidine is negatively influenced in its metabolism by inhibition of oxidation.

Whereas numerous reports deal with contraceptive efficacy that is threatened by antibiotics and tuberculostatics, namely, rifampicin, little is known about the effects of OCs on antibiotic treatment. Only in the case of ampicillin were no alterations in plasma levels found in pilltakers between days 21 and 28 of the artificial cycle.

Like analgesics, tranquilizers, namely, the benzodiazepine, are among the most frequently used drugs in the Western population. Most of these drugs undergo oxidation, and only a few are metabolized predominantly by conjugation. Analogous to cimethidine, a strong inhibitor of microsomal oxidation, OCs inhibit or at least slow down oxidation and thus lead to a reduction in the clearance rates of the benzodiazepines. Because the activity of microsomal oxidation processes decrease with age and because female sex hormones negatively influence the cytochrome P-450 and P-448 systems, both factors diminish clearance rates of the first group of tranquilizers.

In contrast, those benzodiazepines that undergo conjugation as their main metabolic pathway experience a higher clearance rate in OC-treated subjects. Other benzodiazepines, such as clotiazepam and triazolam, showed no pharmacologic changes from OCs.[5, 6]

For the practical clinician, the question arises whether and to what extent pharmacokinetic interactions between OCs and benzodiazepines correspond to clinical interactions. A significant delay in psychomotor impairment of OC users compared with nonusers, which was observed by Ellinwood et al.[7] did not show any correlation with the plasma levels of diazepam, which had been found to be elevated in women and OC users compared with men. Contrasting findings were reported by Krobath et al.[8] for alprazolam, triazolam, and lorazepam. Psychomotor changes were most marked in women who were on the pill. However, again plasma levels did not correlate with the observed clinical effect. Therefore, other hypothetic pharmacodynamic interferences must be postulated, such as a direct change in membrane properties, to explain the lack of clinical manifestation of pharmacokinetic findings.

Tricyclic antidepressants, such as imipramine, clomipramine, and chlorpromazine, were suspected of having increased side effects in OC users on the basis of the observations by Prange.[9] It has been demonstrated that the clearance rate of imipramine is negatively influenced by OCs whereas protein binding and half-life are unaffected. Imipramine is metabolized by demethylation and oxidation before conjugation with glucuronic acid; OCs seem to inhibit oxidation and thus augment bioavailability from 27% to 44%.[10-12] In contrast, clomipramine is not influenced by OCs, although its metabolic rate is enhanced by estrogens and inhibited by gestagens, at least in animal models.[13] The psychotropic effects of sex steroids must be added to the pharmacokinetic interferences. Thus it seems wise to monitor the clinical effects of antidepressants thoroughly if they are given to OC users.

Antiepileptics of the phenytoin type as well as barbiturates are metabolized by oxidation. In addition to influencing the protein binding of phenytoin, OCs lead to a lower oxidation rate in both groups. Since both estrogens and gestagens interfere with amine metabolism in the brain and are known to augment (estrogens) or lower (gestagens) convulsibility, various pharmacodynamic effects are assumed to overlap the clinical manifestations of altered pharmacokinetics.

Indirectly acting anticoagulants, vitamin K antagonists, or coumarin derivatives undergo enzymatic oxidation that is inhibited by cimethidine and induced by phenobarbital. Studies conducted in OC users showed the inhibiting effects of OCs. Moreover, pharmacodynamic interactions may well be of practical importance. Coumarins inhibit the synthesis of vitamin K–dependent coagulation factors VII, IX, and X. Estrogens, namely, orally administered EE, stimulate various coagulation and fibrinolytic agents, in particular factors VII and X, and thus lead to a partial functional antagonism. The net effect of pharmacokinetic and dynamic interferences depends not only on EE dose but also on the type and dose of the gestagen. Because the influence of vitamin K antagonists is the limiting factor in anticoagulatory therapy, OCs clearly weaken their effect.

The potency of OCs to induce or exaggerate elevated blood pressure is well known. EE and gestagens, with the exception of progesterone, cause water and sodium retention and act by way of antidiuretic hormone and aldosterone. The predominant influence is that of EE on the synthesis of renin substrate, thus stimulating the renin angiotensin aldosterone system. Other sites of action of estrogens may be in the heart muscle and the vessel wall. Antihypertensive drugs show great het-

erogenity in their chemical structure and modes of action. Because OCs influences blood pressure regulation, pharmacodynamic interactions are to be expected, particularly if pill-induced forms of hypertension are concerned.

β-Receptor blockers, such as metroprolol, oxprenolol, and propranolol, undergo oxidation that is inhibited by OCs, leading to higher bioavailability. Acebutolol kinetics do not interfere with OCs since this drug undergoes unmetabolized renal elimination. The interaction of an OC with centrally acting antihypertensives such as clonidine may be mediated by α-adrenergic and dopaminergic receptors. Pharmacokinetic interactions are not known.[14]

Clofibrate is commonly used in subjects with hyperlipidemia. Its glucuronidation rates are elevated by OCs, leading to a 48% increase in the clearance rate. Thus the pharmacologic effect of clofibrate is weakened. However, the well-known pharmacodynamic influence of estrogens and gestagens on lipid and lipoprotein metabolism should not be neglected. It largely depends on the type of contraceptive pill and on a great variety of pretherapeutic conditions that have been mentioned above. A general statement that subjects treated for hyperlipidemia should not receive OCs cannot be made at this time on the basis of pharmacokinetic and pharmacodynamic interferences. It is still not clear which OCs have effects on the different forms of hyperlipidemia, what these effects are, and how treatment results are modified by OCs.

In contrast to lipid and lipoprotein metabolism, the pharmacodynamic influences of OCs mainly relate to gestagen interference with *antidiabetic* treatment. Gestagen-induced peripheral insulin resistance may lead in some cases to dose adaptation of insulin. Oral antidiabetic drugs are not likely to be prescribed to juvenile diabetics, which may account for the vast majority of diabetic patients being on the pill.

Of the various hormonal treatment regimens, glucocorticoids are among the most frequently prescribed drugs. It is well known that cortisone-binding globulin and the levels of endogenous cortisol are elevated by EE. Since Spangler et al.[15] reported a two-fold to 20-fold increase in the antiinflammatory effects of topical hydrocortisone on OC users, it has been established that estrogens may well influence the ratio of free and protein-bound glucocorticoids. The mechanism of estrogen action as described for prednisolone seems not only to act by altered protein-binding patterns between cortisol-binding globulin and albumin but also by an inhibited metabolism of prednisolone, mainly because of reduced microsomal oxidation. No influences on pharmacokinetics have been found for fluocortolone.

Substances that are characteristic for specific metabolic processes may be regarded as "markers," in addition to their therapeutic properties. Such markers are theophylline and derivatives, caffeine, and alcohol.

Theophylline undergoes oxidation by cytochrome P-450 and P-448–dependent systems. Both oxidation and clearance rates are lowered by OCs. Because smoking exerts an enzyme-inductive effect, inhibitory actions of OCs on theophylline metabolism are not observed in smoking subjects who are on the pill. The enzymatic and metabolic link between OC and tobacco action, however, remains uncertain.[16, 17]

Caffeine metabolism is mediated by cytochrome P-440 oxidation. As with theophylline, the clearance rates for caffeine are negatively influenced by OCs.

The findings concerning alcohol and alcohol dehydrogenase activity and interaction with OCs are not clearly defined. Decreased elimination rates are not likely to result from OC-induced cytochrome P-450 inhibition, to which only a minor metabolic fraction is subjected. Clinically relevant conclusions cannot be drawn at this time.[18, 19]

OCs exert influences on various vitamins and minerals. Increased plasma levels of iron, copper, and vitamins A, D, and K were found in OC users, whereas concentrations of zinc, folic acid, and vitamins B_1, B_6, B_{12} and C decreased with the use of estrogens and gestagens.[20-27] Whereas in subjects with normal dietary habits these effects will not be clinical relevant, under deprived conditions, reduced plasma levels of essential factors may be of some concern.

In conclusion, as noted above, the effects of oral contraceptives on drug therapy are related mainly to the inhibition of microsomal oxidation and demethylation, as well as the induction of enzymes involved in conjugation reactions. Drugs that share these metabolic pathways will be affected in their pharmacokinetics.

However, various pharmacodynamic interferences between OCs and the effects of other drugs may, in most instances, be counterbalanced with kinetic alterations, resulting in a weak or no obvious clinical manifestations. Attention should be paid mainly to a possible modification of the pharmacologic effects in treatment with antidepressants antihypertensives, insulin, synthetic glucocorticoids, theophylline, and caffeine. Even if such interactions may not be present in all subjects, clinical consequences must be drawn, particularly in predisposed persons.

Oral contraception in disease states

M. Breckwoldt, P. Wieacker, and F. Geisthövel

Freiburg im Breisgau, Germany

Oral contraceptives are clearly contraindicated in patients with a history of thromboembolic disease, ischemic heart attack, or cerebral stroke. Patients requiring long-term anticoagulant treatment can be treated with gonadotropin-releasing hormone analogs to prevent ovulation, because ruptured follicles can cause massive intraperitoneal bleeding. Patients with essential hypertension and severe liver diseases should also discontinue treatment 4 weeks before major elective surgery. Migraine and diabetes mellitus are regarded as relative contraindications, depending on the individual situation. Long-term diseases, such as Crohn's disease, epilepsy, and sickle cell anemia, also require individualized consultation. (Am J Obstet Gynecol 1990;163:2213-6.)

Key words: Oral contraceptives, thromboembolic disease, ischemic heart attacks, essential hypertension, severe liver disease, diabetes mellitus

The use of oral contraceptives (OCs) in disease states and during drug therapy requires consideration of absolute and relative contraindications. This article will concentrate on the various forms of long-term diseases and discuss if the administration of OCs is justified for

Table I. Absolute contraindications

Arterial or venous thrombosis
Ischemic heart disease
Cerebral hemorrhage
Protein C and protein S deficiency
Antithrombin III deficiency
Hypertension
Hypercholesterolemia
Severe liver diseases
Estrogen-dependent breast cancer
Elective surgery

Table II. Relative contraindications

Migraine
Diabetes
Crohn's disease
Epilepsy
Sickle cell disease

each disease or if other alternative methods of contraception are preferred.

Absolute contraindications to OCs are listed in Table I. There is general agreement that OCs are clearly contraindicated in patients with a history of arterial or venous thrombosis, ischemic heart disease, cerebral hemorrhage, and stroke. Epidemiologic data provide evidence of an increased relative risk of venous thromboembolism in otherwise healthy OC users. No consensus has been reached for the risk of ischemic heart disease or cerebral stroke in OC users. Thromboembolic complications can be attributed to the fact that ethinyl estradiol can increase plasma levels of blood clotting factors (factors II, VII, and X) associated with a decrease in antithrombin III concentrations.[1-3] Consequently, patients with hypercoagulability caused by inherited defects of the clotting system, such as protein C, protein S, or antithrombin III deficiency, should be excluded from using OCs, because these patients tend to develop thromboembolic complications. Patients with a history of thromboembolic disease require long-term anticoagulant treatment. However, ovulation under these conditions can lead to massive intraperitoneal hemorrhage. In recent years, five patients receiving long-term warfarin treatment were admitted to our department in severe hemorrhagic shock. Abdominal surgery revealed heavy intraperitoneal bleedings from ruptured follicles or corpora lutea.[4] Pregnancies occurring during treatment with warfarin are of particular concern, because teratogenic effects have been described.[5] Therefore ovulation and pregnancy should be prevented in these patients. To suppress ovulation, these patients can be given a combined gonadotropin-releasing hormone analog/progesterone regimen.[4, 6] Low-dose treatment with gonadotropin-releasing hormone analogs (Buserelin), nasally applied, suppresses luteinizing hormone surges, whereas basal ovarian estrogen secretion is maintained. Analogs of gonadotropin-releasing hormone are devoid of undesirable metabolic side effects. Side effects associated with the use of gonadotropin-releasing hormone analogs are related only to estrogen deficiency. Constant endogenous estrogen secretion is sufficient to prevent loss of bone mass and to stimulate endometrial proliferation. To oppose continuous estrogen effects, vaginal progesterone suppositories are applied in a cyclic fashion to induce secretory transformation of the endometrium and consequently menstrual bleeding.[6] Progesterone is also free of unwanted metabolic side effects.

This approach to birth control is of course limited to a selected group of patients who are at high risk for thromboembolic complications and require careful monitoring. In more than 400 cycles, the pattern of menstrual bleeding was acceptable; only one pregnancy occurred.[6]

Hypertension is also regarded as a contraindication, because OCs can induce elevated blood pressure, presumably by stimulation of hepatic angiotensinogen production, leading to activation of the angiotensin-renin-aldosterone system.[7, 8] OC-induced hypertension is fully reversible after discontinuation of the drug. Patients with a blood pressure of 140/90 mm Hg should be excluded from the use of OCs, because these patients are at increased risk of having hemorrhagic stroke. Monitoring of blood pressure before the prescription of OCs and during OC intake is mandatory. Consequently, essential hypertension is considered an absolute contraindication. However, pregnancy-related hypertension does not correlate with OC intake in this regard.[9] Patients with a history of pregnancy-induced hypertension remain generally normotensive during OC intake. Gestagen-only pills or intrauterine devices can be recommended as alternative methods to prevent pregnancies in patients with essential hypertension.

Inherited hypercholesterolemia is also considered a contraindication to the use of OCs, because patients with chronically elevated cholesterol levels tend to develop arteriosclerosis and consequently hypertension.[10] These patients are also at increased risk for developing ischemic heart disease and myocardial infarction. However, the low-dose OCs presently used do not affect the lipoprotein pattern adversely; the high-density lipoprotein/low-density lipoprotein cholesterol ratio remains within normal limits. "The lower the steroid doses and the more balanced the ratio of progesterone to EE_2, the smaller the change in lipid levels from pretreatment values."[11] The prescription of OCs in these patients should be oriented according to vascular conditions.

Severe liver diseases, including porphyria and benign

liver tumors (adenomas), are contraindications to the use of OCs. Benign liver lesions can be induced by 17-acylated synthetic steroids in rare instances.[12] The incidence of benign liver tumors among OC users has been calculated in the order of 1:200,000.[12, 13] A causal relationship between the intake of OCs and the development of liver lesion is evidenced by the fact that these tumors regress significantly after discontinuation of the pill. We have followed three patients with benign liver tumors, which were probably induced by OCs. In all three patients the tumor regressed remarkably after discontinuation of the drug. The size of the tumor was followed by ultrasonography. Subsequently, these patients became pregnant. All three pregnancies were uneventful, the infants developed normally, and the size of the liver tumors did not increase during pregnancy.[14] This clinical observation indicates that in contrast to synthetic sex steroids, naturally occurring steroids, even in extremely high concentrations, can be metabolized easily by the human liver.

OC use is clearly contraindicated in patients with estrogen receptor–positive breast cancer, because pharmacologically active estrogens may stimulate tumor progression.

Major elective surgery is associated with an increased risk of deep venous thrombosis and pulmonary embolism. Therefore it is advisable and is officially recommended to discontinue the use of OCs 4 weeks before a surgical procedure.[15, 16] This recommendation, however, has been questioned by others.[17] Emergency surgery with subsequent immobilization of the patient requires immediate discontinuation of the pill; prophylactic heparin treatment should be considered.[18]

Relative contraindications to the use of OC are listed in Table II. Migraine should be considered a relative contraindication, because epidemiologic studies indicate an increased incidence of headache attacks during the intake of OCs.[17] In addition, patients tend to be at increased risk of thrombotic stroke. If, however, migraine is temporally related to menstrual bleeding, OCs can be prescribed. A tricyclic regimen is recommended, and the patient is advised to take the pill continuously for 3 months, followed by a 7-day pill-free interval.[19, 20]

Patients suffering from focal migraine caused by transitory cerebral ischemia requiring long-term ergotamine medication should refrain from the use of OCs.[19]

The administration of OCs to diabetic patients has been discussed extensively in the literature. Numerous clinical studies are related to this subject, because it was anticipated that orally active sex steroids might increase peripheral insulin resistance. Whereas exogenous estrogens do not interfere with carbohydrate metabolism, gestagens can reduce cell responsiveness to insulin, leading to slightly elevated circulating insulin levels.[21] The diabetogenic effect of progestogens is caused by a change in insulin receptor binding or a postreceptor defect.[22] Chronically elevated glucose levels lead to inhibition of lipolysis and cholesterol synthesis, resulting in the development of atherogenic lesions. The use of low-dose OCs seems effective in decreasing alterations in carbohydrate metabolism compared with high-dose formulations.[23] However, even low-dose preparations must be considered amplifiers of risk factors.[24] Meanwhile there is general consensus that an otherwise healthy young diabetic patient can use low-dose OCs for a limited duration without being at risk of worsening the metabolic conditions. However, careful monitoring of these patients is required. Vascular lesions related to the diabetic disease are considered absolute contraindications to further use of OCs.

Crohn's disease is also listed as a relative contraindication. According to the data of the Royal College of General Practitioners' cohort study,[25] there is evidence that the incidence of Crohn's disease was increased by 40% in OC users. In addition, in a case-control study,[26] the incidence of Crohn's disease was doubled in women taking OCs. Therefore precautions in prescribing OCs to these patients must be taken.

Epilepsy requires long-term treatment with antiepileptic drugs. All commonly used compounds for the treatment of this disease are considered hepatic enzymes inducers. Therefore increased OCs doses may be necessary.[20] Another alternative is the tricyclic regimen. The frequency of epileptic attacks can be reduced by maintaining steady hormone levels.[20] In addition, it is advisable to reduce the pill-free interval to 4 to 5 days. Furthermore, the cycle should be monitored carefully by keeping a menstrual diary. Breakthrough bleedings indicating enzyme induction require increased doses of ethinyl estradiol.

Sickle cell disease is associated with an increased risk of thrombosis. Therefore OCs should not be used, particularly when other risk factors are present.[27]

Conclusion

Prof. Dr. Herbert Kuhl, MD

Frankfurt am Main, Federal Republic of Germany

The program of the symposium on "Pharmacokinetics of Oral Contraceptives and Drug Interactions" was planned to enable comprehensive discussions between basic scientists and clinicians. Even though the appraisal of the clinical relevance of certain in vitro findings remains controversial, it might induce new insights into the mechanism of action of the pill and the cause of adverse effects.

The meeting began with the pharmacokinetics of steroids contained in modern low-dose pills. The discussion focussed on two points, namely, the large intra- and interindividual variations and the rise in steroid levels during multiple intake. Variability is not limited to steroids undergoing first-pass effect and can be observed to a similar extent when the steroids are administered vaginally. When the serum concentrations are measured several times in the same women, a distinct individual pharmacokinetic pattern becomes discernible. Therefore the interindividual variations are in all probability caused by genetic or acquired differences in the metabolic capacity of the liver and the intraindividual variations by short-term metabolic changes induced by environmental factors. It is interesting to know that even during percutaneous or transdermal estrogen replacement therapy, the serum levels of estradiol and estrone vary to a similar degree within a few hours. Regarding the pill, large variations have also been observed in the ratio between the levels of ethinyl estradiol and the prostogen, indicating that changes in the metabolism of estrogens and progestogens must not be parallel and that there is no optimal estrogen/progestogen ratio. The rise in the serum levels of nortestosterone derivatives during multiple intake is well known and was associated with the binding

6/0/23621

of steroids to sex hormone–binding globulin (SHBG), the production of which is increased by ethinyl estradiol. However, some observations have indicated that an inhibition of hepatic metabolism of the progestogens by contraceptive steroids is also involved. The steady-state levels of levonorgestrel and gestodene were higher than those obtained by computer simulation based on single-dose administration. Moreover, during intake of a low-dose combination of 30 μg of ethinyl estradiol and 150 μg of levonorgestrel, the levonorgestrel levels rose, even though the SHBG levels remained unchanged. A similar rise in the serum concentrations was also observed during multiple intake with ethinyl estradiol, which is nearly exclusively bound by albumin. Because albumin is not influenced by the pill and ethinyl estradiol sulfates do not represent a reservoir for ethinyl estradiol on account of a half-life similar to that of ethinyl estradiol, it must be assumed that the increase in the levels of ethinyl estradiol is caused by an inhibition of hepatic metabolism.

Gastrointestinal metabolism plays a role in the pharmacokinetics of steroids undergoing first-pass effect. Ethinyl estradiol is metabolized to a large degree in the gut wall, mainly by sulfate conjugation. Desogestrel and norgestimate, which are prodrugs, are also substantially metabolized in the intestinal tract. The pharmacokinetics of prohormones may differ from that of steroid hormones by the lapse of time until peak levels are reached. While desogestrel is rapidly converted in the gut and liver into the hormonally active metabolite 3-keto-desogestrel, the mechanism of action of norgestimate is less clear, and the pharmacokinetics of levonorgestrel-17-β-acetate, levonorgestrel-3-oxime, and levonorgestrel, which are metabolites of norgestimate, are only partly known. It has to be taken into consideration that a retarded conversion of a prodrug may avoid high peak concentrations of the active hormone in the liver during the first liver passage and consequently may reduce the influence of the hormone on hepatic metabolism.

It is assumed that steroid distribution between various protein-bound and non-protein-bound components in serum may influence their bioavailability at target cells and their elimination rate. Contrary to ethinyl estradiol, which is bound with low affinity to albumin, the nortestosterone derivatives are more or less tightly bound to SHBG. Both levonorgestrel and gestodene are bound with high affinity to SHBG, whereas 3-keto-desogestrel is markedly less and norgestimate and levonorgestrel-3-oxime are not at all bound to SHBG. However, the role of serum protein binding in the control of pharmacokinetics and pharmacodynamics still remains a matter of controversy, because, on the one hand, binding proteins has been suggested to be involved in the process of steroid uptake by target cells, and on the other hand, association to and dissociation from binding proteins is a dynamic process that is markedly influenced by the concentration gradient of the steroid between blood and cell. Consequently, the inactivation rate within the cell and the specific binding to receptors or proteins in the cytoplasm or nucleus play an important role. Nuclear receptor binding of steroids is the principal determinant of biologic action, and because the number of specific receptors is limited, full occupation and maximal response may occur at relatively low hormone concentrations. The involvement of serum protein binding in the control of hepatic inactivation and elimination remains obscure, because levonorgestrel and gestodene are bound by SHBG with similar affinities, but only gestodene accumulates in the blood to such an extent that extraordinarily high serum levels are reached despite the lowest dose contained in an oral contraceptive.

Ethinyl estradiol is predominantly metabolized by hydroxylation of the aromatic ring A. The relevance of irreversible binding of the synthetic estrogen to proteins and deoxyribonucleic acid remains unresolved. The pathway of these chemical reactions, which may also affect hepatic enzymes, is unclear, but oxidative conversion of 2-hydroxy-ethinyl estradiol into a reactive intermediate seems to be involved. Steroids containing an ethinyl group are capable of inactivating hepatic cytochrome P-450-dependent enzymes, which are responsible for oxidation and demethylation of steroids and drugs, such as the 2-hydroxylation of ethinyl estradiol. It was demonstrated in vitro and in vivo that after oxidative conversion of the ethinyl group, the reactive intermediate binds irreversibly to the heme group of the cytochrome that is destroyed. With the use of human liver microsomes, several ethinylated steroids were found to be mechanism-based inactivators (suicide inhibitors) of cytochrome, among which gestodene was the most potent. The chemical reactions of activated intermediates, both at the aromatic ring A and the ethinyl group, may be responsible for the rise in steroid levels during multiple intake of contraceptive steroids. The inhibitory action of high gestodene concentrations, particularly during first liver passage, might be causative for the higher serum concentrations of ethinyl estradiol during treatment with a combination of 30 μg ethinyl estradiol and 75 μg of gestodene compared with those with 30 μg of ethinyl estradiol and 150 μg desogestrel.

Drugs may interact with the pharmacokinetics of steroids by induction of hepatic enzymes, resulting in an enhanced metabolism of contraceptive steroids that may impair contraceptive effectiveness. On the other hand, oral contraceptives may inhibit drug-metabolizing enzymes, resulting in a prolongation of half-life and an increase in the serum concentrations of a series of drugs. The clinical relevance of these effects is not clear, but an enhancement of the adverse

effects of imipramine during concomitant treatment with oral contraceptives has been reported.

Antibiotics may interfere with the enterohepatic recirculation of ethinyl estradiol by destroying gut flora. Because intestinal bacteria may develop resistance to the antibiotic within several days, the effect may be transitory. There is little direct conjugation of progestogens at the 17β-hydroxy group, and the main metabolic steps are A ring reduction and subsequently conjugation of the 3-hydroxy group. Therefore enterohepatic recirculation of progestogens is of no importance. Because in low-dose oral contraceptives the progestogen component is responsible for ovulation inhibition and contraceptive effects on the cervix and endometrium, treatment with antibiotics may cause irregular bleedings by reducing the estrogen level but may hardly impair contraceptive safety, provided that the pill is taken correctly and the antibiotic does not induce steroid-metabolizing enzymes in the liver.

Two aspects must be considered when oral contraceptives are applied in a disease state; the most important problem is the absolute and relative contraindications, for example, in patients with thromboembolic or liver disease in their history, whereas impairment of the contraceptive effect may result from reduced absorption in patients with gastrointestinal diseases. The bioavailability of steroids is not affected by antacid administration, and neither diarrhea of colonic origin nor ulcerative colitis was found to influence absorption. Whether ileostomy or proctocolectomy may reduce bioavailability remains to be clarified. Oral contraceptives are contraindicated in patients with a history of thromboembolic disease, ischemic heart attack, or cerebral stroke. Administration of the pill should be discontinued 4 weeks before elective surgery. During long-term anticoagulant therapy, ovulation should be prevented, since ruptured follicles can cause massive intraperitoneal bleeding. In these patients treatment with a potent luteinizing hormone–releasing hormone analog should be a suitable method. Essential hypertension and liver disease are also contraindications, as well as hypercholesterolemia, which often is associated with atherosclerosis and an increased risk of myocardial infarction.

Pharmacodynamics include both receptor-mediated effects and receptor-independent actions on enzymes and other proteins, on membranes, and so forth. When potent sex steroids are used, receptor-mediated hormonal effects may reach an upper limit at relatively low serum concentrations. In this case it will be difficult to substantiate significant differences in the effect of, for example, different progestogens. A similar problem is the possible effectiveness of endogenous estradiol produced by developing follicles during treatment with low- or high-dose oral contraceptives. Although occupation of a relatively small portion of estrogen receptors may trigger the maximal biologic effect in some target tissues, it cannot be excluded that high estradiol levels may contribute to side effects such as mastalgia. It remains to be clarified whether during the elimination phase of the time-versus-concentration curve with decreasing ethinyl estradiol levels, endogenous estradiol may become effective. On the other hand, mastalgia might also be the result of insufficient action of the progestogen component, which at the same time is the cause of follicular activity.

Contrary to this, receptor-independent effects, such as irreversible interactions of ethinylated steroids with proteins and other functional units, are largely dependent on dose and concentration. They may well explain the toxic effects of ethinylated steroids on the liver during chronic treatment, which has been known for many years.

Although the papers presented at this symposium and the intensive discussions that followed have clarified some questions concerning the action and safety of oral contraceptives, the questions that have newly emerged are more than those that could be answered. The factors responsible for the large day-to-day variations in the steroid levels and the hepatic metabolism remain to be investigated; mental and physical stress, diet, and drugs may be involved. Deficient knowledge also surrounds the role of target cell metabolism and storage in fat tissue. Could ethinyl estradiol be transported in lipoproteins after esterification with fatty acids? Is there a change in the pharmacokinetics with age?

The most important conclusion of the symposium might be that obviously the development of the pill has not yet reached an endpoint, as was claimed after the introduction of the recent low-dose oral contraceptives, and that new concepts are necessary.
